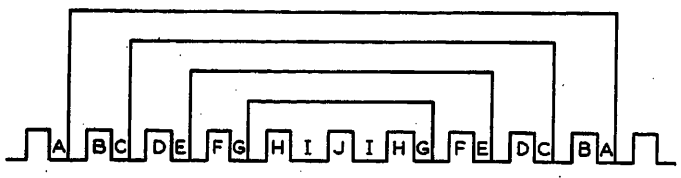

**Figure 6. Winding distribution; 9 slots per pole wound over 3, 5, 7, and 9 teeth**

Since in production it is desirable to wind the smaller coils with less turns the winding of motors for sinusoidal wave form is further desirable. It appears at present that this method can also be applied to windings where the poles overlap provided a half coil is used for the outer coil. The angle for this coil would always be 90 degrees and the sine of 90 degrees is one. A calculation with a full coil would be an impossible winding since there would be no slot room for the adjacent pole except in light starting windings. Furthermore, it would not give a very good wave form. By using half the value a practical winding is secured

| | 23 | − 2.34 | − 4.534 | 0.482 | − 5.514 | 3.175 | − 5.017 |
| | 25 | − 2.92 | − 0.444 | − 4.616 | 2.153 | − 5.073 | 4.172 |
| | 27 | − 3.333 | 3.333 | − 3.333 | 3.333 | 3.333 | − 3.333 |
| | 29 | − 3.596 | 4.373 | 1.855 | − 3.979 | 0.383 | 2.518 |
| | 31 | − 3.723 | 2.356 | 4.092 | − 0.358 | − 3.365 | − 1.736 |
| | 33 | − 3.727 | − 0.998 | 0.998 | 3.727 | 3.727 | 0.998 |

and one with more nearly a sinusoidal wave form. In a motor using 9 slots per pole we would then calculate the percentage of the total turns per pole for each slot as follows when using a winding over 3, 5, 7, and 9 teeth.

sine 3/9 × 90 degrees = sine 30 degrees = 0.500/3 teeth.
sine 5/9 × 90 degrees = sine 50 degrees = 0.766/5 teeth.
sine 7/9 × 90 degrees = sine 70 degrees = 0.940/7 teeth.
1/2 sine 9/9 × 90 degrees = 1/2 sine 90 degree = 0.500

100 per cent = 2.706

Percentage of turns over 3 teeth = 0.50/2.706 = 18.5 per cent
Percentage of turns over 5 teeth = 0.766/2.706 = 28.3 per cent
Percentage of turns over 7 teeth = 0.940/2.706 = 34.7 per cent
Percentage of turns over 9 teeth = 0.50/2.706 = 18.5 per cent

100.0 per cent

The few minutes spent to determine how a winding should be distributed are well spent. Instead of depending on a lucky guess mathematics is used.

* *A* is 0.122 over 2, 0.226 over 4, 0.306 over 6, and 0.346 over 8 teeth
** *B* is 0.258 over 4, 0.348 over 6, and 0.394 over 8 teeth
† *C* is 0.167 over 5, 0.333 over 7, and 0.500 over 9 teeth. (This is the same as 1–2–3 over 5–7–9)
†† *D* is 0.185 over 3, 0.283 over 5, 0.347 over 7, and 0.185 over 9 teeth

Table XV showing the relative strengths of the different harmonics of the above winding distribution shows how small the harmonics are. This table also shows a number of other possible distributions, some with harmonics as high as 10 to 20 per cent of the fundamental. That this is an undesirable condition from both a torque and noise standpoint need hardly be mentioned, but it should bring forcibly to the designer's attention the desirability of distributing the winding for sinusoidal wave form.

My suggestion to the designer is to calculate the percentage of total turns in each slot for the various distributions he most frequently uses. He will then refer to this sheet when calculating each new winding. I am including the most common distributions in table XVI. For the man who wants to figure the strength of the harmonic fields, I suggest that he also make a set of tables for the strength of the various harmonics for the individual coils of the pole.

The strengths of the various harmonics for each individual coil of the pole are figured and are added algebraically to get the strength of the various harmonics for the complete pole. Careful attention must be paid to the signs.

I am including some of my tables with this article to help the designer. He will very probably note that there are 2 harmonics which regardless of the method of winding distribution he cannot overcome. The number of these harmonics is twice the number of stator slots per pole plus or minus one. If, for example, 9 slots per pole are used the seventeenth and nineteenth harmonics cannot be eliminated regardless of how the motor is wound. They can, however, be skewed out. This will be discussed under the subject of skew.

It should also be mentioned that it is at times necessary for the designer to secure special results as for example in the design of a 2-speed motor. He usually develops what is known among engineers as a freak circuit. When this is the case it is sometimes so complicated and impossible to calculate the various harmonics present that he usually goes back to the method of cut and try. Needless to say, some of the motors using these circuits are very noisy.

## Skew

We have already discussed the selection of the proper number of rotor bars and the winding distribution to secure nearly sinusoidal wave form. We noted in the

section on wave form that there were 2 harmonics always present regardless of how we wound the stator.

We know that if we want to get a current flow in a wound armature we must put one side of each coil under a north pole and the other side under a south pole. If we should place both sides of the coil under like poles no current would flow. One theory of skew is based exactly on this idea. Referring again to our case of 9 slots per pole we have the seventeenth and nineteenth harmonics present regardless of the method of winding. We shall assume that there are no other bad harmonics because proper winding distribution was used. Since the fundamental has 4 poles the seventeenth and nineteenth harmonics have 68 and 76 poles, respectively, or 34 and 38 pairs of poles. It is now our object to place one end of the rotor bar under one north harmonic pole and the other end under another north harmonic pole. This will prevent any current flowing in the rotor caused by the harmonic pole.

The rotor should be skewed 1/34 of the entire rotor to eliminate the seventeenth harmonic and 1/38 of the entire rotor to eliminate the nineteenth harmonic. If we were using a 44-bar rotor the skew to eliminate the seventeenth harmonic would be 1/34 times 44 equals 1.29 bar skew. To eliminate the nineteenth harmonic we would need 1/38 times 44 equals 1.16 bar skew. If the rotor were held as nearly commercially as possible to these limits there should be little trouble caused by the seventeenth and nineteenth harmonics. Now that we have pointed out the best skew from a harmonic viewpoint let us point out the

worst. This condition exists when one end of the rotor bar lies under a north harmonic pole and the other end under a south harmonic pole. Since the seventeenth harmonic has 68 poles and the nineteenth has 76 poles the worst condition would be 1/68 times 44 equals 0.645 bar skew and 1/76 times 44 equals 0.58 bar skew.

Another condition that would not be good but which is better than the one just described is the existence of a 3-harmonic pole skew. This skew would be 3/68 times 44 equals 1.94 bars for the seventeenth harmonic and 3/76 times 44 equals 1.73 bars for the nineteenth harmonic. With this condition one end of the rotor bar would be under a north pole and the other end under a south pole. However, since the point one-third of the distance from the one would be under a pole of the same polarity as the beginning of the bar there would be a tendency to prevent a current flow in 2/3 of the bar.

Another factor to keep in mind when figuring skew is the effect of skew on the various modes of vibration of the frame as discussed by S. J. Wikina. There are 4 modes of vibration. The energy input per pole to the first, second, and fourth modes of vibration is zero with a skew of 1, 2, or any integral number of slot pitches. The maximum energy input with over one bar skew is never greater than 20 per cent of that with no skew. To eliminate the third mode of vibration it is necessary to have a skew of 1.43 bars or to have the number of rotor bars divisible by the number of poles. The energy is maximum at 2/3 bar skew. This is the most critical of the 3 modes rising rapidly on either side of the zero energy point. If, therefore, it is possible to eliminate the third mode of vibration by having the number of rotor bars divisible by the number of poles this third mode will be completely eliminated and the first and second will be lessened. Then by skewing the rotor one bar or more the first, second, and fourth modes will either be eliminated or made quite small. While I have never personally designed a quiet motor with this last method in mind, the engineer studying this paper will note that some of the designs discussed fulfill at least to some extent the requirements by meeting other requirements set forth in the earlier part of this work. The 44-bar rotor when used on a 4-pole motor is divisible by the number of poles. The same applies to the 20- and 34-bar rotors of the 2-pole motor. Since I never use less than one bar skew except on very short armatures other difficulties have been avoided.

In summarizing, there are some general statements that it is well to bear in mind.

1. Be sure the motor is built carefully in production.
2. The winding should be distributed so that all but 2 harmonics are eliminated.
3. The rotor should be skewed to eliminate these 2 harmonics and not less than one bar.
4. The number of rotor bars should be carefully selected so there will be no harmonics with a 2-pole difference. It may be advantageous to use a rotor with the number of bars divisible by the number of poles where necessary.
5. There should be no magnetic parts extremely light that will vibrate excessively. This especially refers to teeth and tooth tips.

Tables IV to XVI were calculated in 1917. They give the center ordinate value of the sinusoidal magnetomotive forces produced by a current of the instantaneous value of one ampere in a coil of 100 turns for the fundamental and all harmonics to the 33rd inclusive. The formula used for this calculation is:

$$h_m = \frac{4In_0}{m\pi} \times \sin\frac{m\pi}{2} \sin\frac{m\lambda\pi}{2}$$

in which

$h_m$ is the center ordinate value of the $m$th harmonic
$I$ is the value of the current at the given instant
$n_0$ is the number of turns per coil
$m$ is the order of the harmonic
$\lambda$ is the pitch expressed as a decimal fraction

The tabulated values are for a single coil. For distributed windings the resultant for the whole winding may be found as follows: For concentric windings, take from the tables the values for each of the coils separately, then add the respective values, with due regard to sign. The result will be the resultant of the whole winding. For diamond windings, multiply the tabular values for the center ordinate, by the expression

$$\frac{\sin\frac{m\pi}{2p'}}{\sin\frac{mp'}{2M_{sp}}}$$

in which $p'$ is the number of phase belts per pole and $M_{sp}$ is the number of slots per pole. The values of this factor are very easily calculated. This gives magnetomotive force per phase belt.

For single phase or 2-phase windings, concentric or diamond, the magnetomotive force per phase belt is also the magnetomotive force for the entire stator winding. For three-phase windings, the magnetomotive force for the entire winding is found by multiplying the magnetomotive force per phase belt by the factor $(p'/2)$ except for the harmonics whose number is divisible by 3, for which the factor zero is to be used; the latter harmonics are therefore not present in 3-phase windings.

This method was first published in *Electrical World*, August 26, 1909.

# A Formula for the Reactance of the Interleaved Component of Transformers

By H. B. DWIGHT
FELLOW AIEE

L. S. DZUNG
NONMEMBER AIEE

THE REACTANCE of a power transformer is materially changed when connection is made to taps of different voltages. This can be computed for concentric, core-type transformers by dividing the winding into a concentric component and an interleaved component according to the method of H. O. Stephens.[1]

The concentric component is an assumed transformer winding in which the secondary ampere-turns are equal and opposite to the primary ampere-turns for each centimeter along the axis. The cylinder of winding of the actual transformer which has no part tapped out, is taken as one of the windings of the concentric component. The other winding of the concentric component matches the first exactly in ampere-turns per centimeter along the axis, magnetizing current being left out of consideration.

The interleaved component of winding is what is needed to be added to the concentric component to make the total equal to the actual transformer for the particular connection considered. Nothing needs to be added to the cylinder which has no part tapped out and so the interleaved component is a single cylinder. Its positive and negative ampere-turns are equal and opposite. See figure 1 and the descriptions in reference 1.

It is evident, from the simple rules just given by which the interleaved component is defined, that the number of ampere-turns of the parts of the interleaved component of winding, and their location, can be easily determined without any special formulas. Examples are clearly illustrated in reference 1. See also example I of this paper.

The leakage reactance $X$ of a transformer when expressed in ohms is referred to either the primary side or the secondary. This is the same as finding the leakage reactance in ohms of a one-to-one ratio transformer. If $I$ is the current of the side taken, the stored energy of the leakage magnetic field is $I^2X$ and is equal to the summation of $H^2/8\pi$ for every cubic centimeter of the leakage magnetic field. Magnetizing current is taken equal to zero, or in other words the iron is assumed to have zero reluctance so far as the computation of leakage reactance is concerned.

If the primary and secondary of the one-to-one ratio transformer are connected in series and the current $I$ is sent through them in the proper directions, the magnetic field will be the same as the leakage magnetic field, because it is produced by the same currents. $H^2/8\pi$ will be the same and the stored energy $I^2X$ will be the same. But $X$ is now $2\pi fL$ where $L$ is the self-inductance of the complete circuit. This provides a method for computing $X$, which is used in the appendix.

Since the ampere-turns of the concentric and interleaved components are together equal to the ampere-turns of the actual transformer, the summation of $H^2/8\pi$ when both are carrying current gives $I^2X$ for the transformer. The magnetic field of the concentric component is chiefly axial where the density is greatest and the most energy is stored, and the densest parts of the field of the interleaved component are radial. See figures 2 and 3, reference 1.

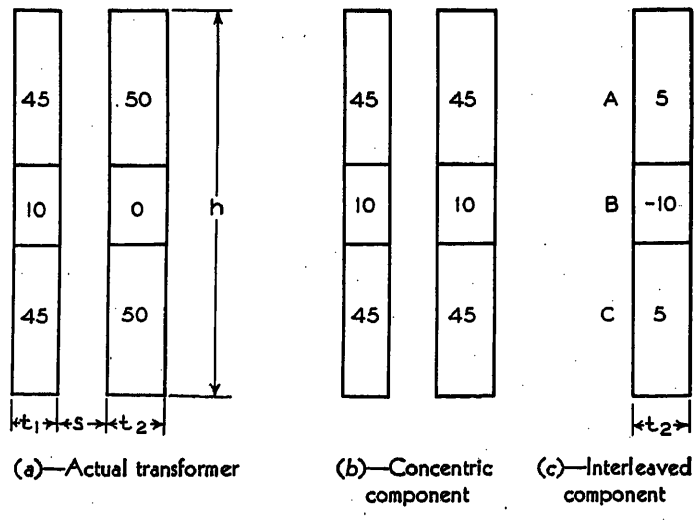

**Figure 1. Cross section of core-type transformer winding**

The fields of the 2 components are chiefly at right angles.

In any cubic centimeter, the stored energy of 2 fields $H_1$ and $H_2$ which are at right angles is $(H_1^2 + H_2^2)/8\pi$. As a consequence, the reactances of the concentric and interleaved components may be computed separately and added together to give, very nearly, the reactance of the tapped-out transformer. See the discussion by A. Boyajian, ELECTRICAL ENGINEERING (AIEE TRANSACTIONS), 1934, page 1318. This has been shown to be a close approximation, by comparing the result with the transformer reactance computed by methods not involving the division into concentric and interleaved components. Tests on practical transformers also have shown the accuracy of the method. See the discussion by A. N. Garin, ELECTRICAL ENGINEERING (AIEE TRANSACTIONS), 1934, page 1319.

The study of interleaved components has shown that the reactance can be reduced and the eddy-current losses

A paper recommended for publication by the AIEE committee on electrical machinery. Manuscript submitted July 12, 1937; released for publication September 30, 1937.

**Figure 2. Curves for reactance of interleaved component**

$a$ = ratio of height of middle rectangle to $h$

$X_t = KfmT^2 10^{-9}$ ohms per leg

in the copper minimized, by thinning out the turns in one winding opposite the tapped-out section of the other winding. See reference 1. This reduces the radial flux or "cross flux." The definition of interleaved component which has been given applies quite well to the case of thinned out transformer windings and so no special arrangements are necessary in the computation. All that is needed is to find the ampere-turns of the interleaved component and then the reactance of the 2 components of winding.

The paragraghs up to this point are a review of the material developed by H. O. Stephens in his paper.[1]

The leakage reactance of one leg of a concentric, core-type transformer without tapped-out sections is given very closely by the following well-known formula:[2]

$$X_c = \frac{8\pi^2 N^2 f m_1 10^{-9}}{h}\left(s + \frac{t_1}{3} + \frac{t_2}{3}\right) \text{ ohms} \qquad (1)$$

For the meaning of the letters see figure 1. Also, $N$ is the number of turns of one cylinder of one winding, $m_1$ is the length of mean turn for the transformer, dimensions being in centimeters, and $f$ is the frequency.

For the interleaved component of one leg of a core-type transformer which has one central tapped-out section, as shown in figure 1, find $T$, the number of turns in the tapped-out section in the interleaved component. See the third paragraph of this paper. Then, as derived in the appendix,

$$X_t = \frac{4.605\pi f m T^2 10^{-9}}{a(1-a)^2}\,[(1+a)^2 \log_{10} S_{AB} - (1-a)^2 \log_{10} S_A - 2a \log_{10} S_B - 2a \log_{10} S_{ABC}] \text{ ohms} \qquad (2)$$

The rectangles $A$, $B$, and $C$ are shown in figure 1*c*.

$m$ = mean turn in centimeters of the interleaved component.

$T$ = number of turns in $B$ of the interleaved component.

$a$ = ratio of the axial length of rectangle $B$ to the length of the complete rectangle $ABC$.

$S_{AB}$ = length + width, of the rectangle $AB$, and similarly for the other rectangles.

In figure 2, curves are given by which most of the computation of formula 2 may be avoided.

Formula 2 was derived in connection with thesis work at Massachusetts Institute of Technology.

*Example I.* The transformer shown in figure 1 has a tapped-out portion equal to 20 per cent of the secondary turns. Opposite this part, the primary winding has only 10 per cent of its turns, the winding being thinned out by spacing the individual coils farther apart. If $N$ is the number of turns in one cylinder of the secondary winding when not tapped, then $T$ for formula 2 is 0.1 $N$ when operating on the 80-per-cent tap. When the transformer is operating on the 100-per-cent tap, the numerical value of $T$ is also 0.1 $N$. The figures in figure 1 are percentages.

If the primary winding were not thinned out, then for operation on the 80-per-cent tap the value of $T$ would be 0.2 $N$, and the increase in reactance would be 4 times as great, since it varies as $T^2$.

*Example II.* This utilizes the sample design of a 1,000-kva 575-to-13,800-volt 60-cycle transformer given on page 395 of "Design of Electrical Apparatus," by J. H. Kuhlmann.

The low-voltage winding is considered the primary. It is not thinned out. One-fifth of the turns of the high-voltage winding are tapped out, thus giving 11,000 volts.

The high-voltage windings are taken to be connected in star in this problem.

Mean turn, low voltage, 39.4 inches and high voltage, 53.9 inches.
Thickness of windings, low voltage 1.03 inches, high voltage 1.45 inches.
Insulation space between high and low windings, 1.063 inches.
Length of coils, 23.5 inches.
Number of turns per phase in the untapped high-voltage winding = 512.

The lengths of rectangles $A$, $B$, and $C$, figure 1$c$, are 9.4, 4.7, and 9.4 inches and their width is 1.45 inches. The reactance $X_c$ of the concentric component is computed by 1. It is the same in this case as the reactance of the transformer when it is operated on the 100-per-cent tap.

$$X_c = 8\pi^2 \times 512^2 \times 60 \times 46.65 \times 2.54 \times 10^{-9} \times \frac{1}{23.5}\left(1.063 + \frac{1.03}{3} + \frac{1.45}{3}\right)$$

= 11.83 ohms, referred to the high-voltage side

$$\text{Per cent } X_c = \frac{11.83 \times 41.8 \times 1.732 \times 100}{13800} = 6.21 \text{ per cent}$$

The reactance $X_t$ of the interleaved component is given by 2, the value of $T$ being 102.

$$\log_{10} S_{AB} = \log_{10}(9.4 + 4.7 + 1.45) = \log_{10} 15.55 = 1.19173$$

Inch dimensions are permissible for $S_{AB}$ etc. as described in the appendix.

$$\log_{10} S_A = \log_{10}(9.4 + 1.45) = 1.0354$$
$$\log_{10} S_B = \log_{10}(4.7 + 1.45) = 0.7889$$
$$\log_{10} S_{ABC} = \log_{10} 24.95 = 1.3971$$
$$a = 0.2$$

$$X_t = 4.605\pi \times 60 \times 53.9 \times 2.54 \times 102^2 \times 10^{-9} \times \frac{1}{0.2 \times 0.64} \times [1.44 \times 1.19173 - 0.64 \times 1.0354 - 0.4 \times 0.7889 - 0.4 \times 1.3971] = 1.74 \text{ ohms}$$

This result can be obtained from figure 2, using $a = 0.2$, $t/h = 0.062$ and $K = 20.4$.

$$\text{Per cent } X_t = \frac{1.74 \times 41.8 \times 1.732 \times 100}{13800} = 0.91 \text{ per cent.}$$

Reactance of the tapped transformer = 6.21 + 0.91 = 7.12 per cent

Thus, the reactance is increased about one-seventh by tapping out the section.

The rated input to the tapped transformer is taken to be 1,000 kva at 575 volts, the same as for the untapped transformer, neglecting magnetizing current.

The way in which $N$ and $T$ are used, and the way in which reactance ohms are converted to percentages, should be noted, as the definitions for these items perhaps may be taken most easily from the example.

In order to make an approximate check of the calculations, a $^1/_4$-size model of the transformer coils was made. The reactance of the coils was measured without any iron core. In order to have the reactance larger than the resistance, 530-cycle current was used. The reactance then was corrected for 60-cycle current and for size. The result was 6.3 per cent for the tapped transformer, to compare with 7.12 per cent computed.

A $^1/_4$-size model of the interleaved component of the windings also was made and tested. Its reactance was 1.0 per cent, to compare with 0.91 per cent computed.

This test should be considered as a preliminary, approximate check. The question of the accuracy and usefulness of formula 2 presented in this paper should be settled by its application to the cases of practical power transformers, whose reactance has been accurately tested in the usual way.

## Appendix

### Derivation of Formula 2

The interleaved component has the same number of positive as negative ampere-turns. Assuming that the windings of the 3 rectangles $A$, $B$, and $C$, figure 1$c$, are connected in series,

$$L_t = 2L_A + L_B - 4M_{AB} + 2M_{AC} \tag{3}$$

since $A$ and $C$ are the same size and their current is opposite in direction to that of $B$.

Let $L_{AB}^{(B)}$ = self-induction of $A$ and $B$ connected in series but with current direction and winding density in turns per square centimeter in both the same as in $B$. Let $k$ = ratio of winding density of $B$ to that of $A$.

$$L_{AB}^{(B)} = L_A^{(B)} + L_B + 2M_{AB}^{(B)} \tag{4}$$

since the entire inductive voltage drop in $AB$ is made up of drop in $A$ caused by its own current plus drop in $B$ caused by its own current plus drop in $A$ caused by current in $B$ plus drop in $B$ caused by current in $A$.

$$2M_{AB}^{(B)} = 2kM_{AB} = L_{AB}^{(B)} - k^2L_A - L_B$$

$$2M_{AB} = \frac{1}{k} L_{AB}^{(B)} - kL_A - \frac{1}{k} L_B \tag{5}$$

$$L_{ABC}^{(B)} = 2L_A^{(B)} + L_B + 4M_{AB}^{(B)} + 2M_{AC}^{(B)} = 2L_{AB}^{(B)} - L_B + 2M_{AC}^{(B)}$$

from 4.

$$2M_{AC} = \frac{2}{k^2} M_{AC}^{(B)} = \frac{1}{k^2} L_{ABC}^{(B)} - \frac{2}{k^2} L_{AB}^{(B)} + \frac{1}{k^2} L_B \tag{6}$$

From 3,

$$L_t = 2L_A + L_B - \frac{2}{k} L_{AB}^{(B)} + 2kL_A + \frac{2}{k} L_B + \frac{1}{k^2} L_{ABC}^{(B)} - \frac{2}{k^2} L_{AB}^{(B)} + \frac{1}{k^2} L_B$$

$$L_t = 2(1 + k)L_A + \left(1 + \frac{2}{k} + \frac{1}{k^2}\right) L_B + \frac{1}{k^2} L_{ABC}^{(B)} - \frac{2}{k}\left(1 + \frac{1}{k}\right) L_{ABC}^{(B)} \tag{7}$$

Turns in $B = T$
Turns in $A = T/2$
Turns in $AB^{(B)} = T + kT/2$
Turns in $ABC^{(B)} = T + kT$

$$L_A = 2m \frac{T^2}{4} \log_n \frac{u}{G_A} \text{ abhenries}$$

$$L_B = 2mT^2 \log_n \frac{u}{G_B} \text{ abhenries}$$

$$L_{AB}^{(B)} = mT^2 \frac{(2+k)^2}{2} \log_n \frac{u}{G_{AB}} \text{ abhenries}$$

$$L_{ABC}^{(B)} = 2mT^2 (1+k)^2 \log_n \frac{u}{G_{ABC}} \text{ abhenries}$$

where logn denotes natural logarithm, where $u$ is a certain large distance to which flux is counted and which cancels out later, and where $G_A$ is the self geometric mean distance of the rectangle $A$, and similarly for the other rectangles. This type of computation, which applies quite well for transformer reactance, deals with the reactance per centimeter of the circuit made up of the primary and secondary windings, and it is assumed that the effect of their curvature is negligible.

From 7,

$$L_t = mT^2(1+k) \log_n \frac{u}{G_A} + 2mT^2 \left(1+\frac{1}{k}\right)^2 \log_n \frac{u}{G_B} +$$

$$2mT^2 \left(1+\frac{1}{k}\right)^2 \log_n \frac{u}{G_{ABC}} - mT^2 \left(\frac{2+k}{k}\right)^2 (1+k) \log_n \frac{u}{G_{AB}} \quad (8)$$

From the definition of $a$ following equation 2 and from the fact that the total turns in $A$, $B$, and $C$ of the interleaved component are zero,

$$ka - (1-a) = 0$$

$$k = \frac{1-a}{a}$$

$$1 + k = \frac{1}{a}$$

$$1 + \frac{1}{k} = \frac{1}{1-a}$$

$$\left(\frac{2+k}{k}\right)^2 (1+k) = \frac{(1+a)^2}{a^2} \frac{a^2}{(1-a)^2} \frac{1}{a} = \frac{(1+a)^2}{a(1-a)^2}$$

A very close approximation[3] to the self geometric mean distance of a rectangular area is 0.2235 times (sum of sides). If this is used in 8, the following is obtained:

$$L_t = \frac{2.303mT^2}{a(1-a)^2} [(1+a)^2 \log_{10} S_{AB} - (1-a)^2 \log_{10} S_A - 2a \log_{10} S_B - 2a \log_{10} S_{ABC}] \quad (9)$$

From this, 2 is directly obtained.

The coefficient of logn $u$ in 8 is

$$1 + 2a + a^2 - (1 - 2a + a^2) - 4a$$

which is equal to zero, and so $u$ cancels out. In the same way, 0.2235 cancels out and does not appear in the final formula. Also, if $S_{AB}$, etc., are given in inches, their multipliers 2.54 cancel out, but this does not apply to the dimension $m$, which must always be changed to centimeters.

# "Inside a Metal"

CAREFUL RESEARCH into the nature of the metallic state has yet to discover, with any certainty, its essential quality, says L. R. van Wert, lecturer on metallurgy, Harvard University, Cambridge, Mass., in an article of the above title published in the October 1937 issue of *Mining and Metallurgy*, pages 453–8.

The basic fact underlying nearly all metallic behavior is that a metal is crystalline in its nature; any mass of metal that has been formed in the ordinary way is made up of many small crystals tightly bound together. It is true that a few properties, such as valence and ferromagnetism, are atomic in origin, so one must actually go within the atom for their ultimate source, but excepting these, metallic properties come about through varieties in interatomic organization.

All matter is atomic in nature, and the metals are no exception. However, with respect to the way the atoms are arranged matter is of 2 kinds: isotropic, of which liquids and gasses are examples; and crystalline, of which metals are examples. The crystalline state of matter is characterized, first, by a lower total energy than the isotropic form, and secondly, by the atoms being essentially at rest, and in regularly and definitely spaced positions. This regularity in atomic spacing confers on the crystal a definite internal architecture in which a certain pattern, often quite simple, is indefinitely repeated. This unit pattern is called the space lattice; the first word indicates that one is dealing with 3 dimensions, and the second suggests a rigid framework on which the atoms hang. The bonds are electrostatic in nature and electronic in origin.

It is not easy to create a simple physical picture of metal linkage [or bonding in metal], but in briefest outlines the picture is somewhat as follows: Because there are not sufficient valency electrons for the atoms to form groups among themselves by either the ionic or covalent manners of bonding, it becomes necessary for the electrons to act for several atoms. Like covalent bonding, metal linkage is one of electron sharing, but differs from it in that the sharing is really quite free and unrestricted. One may then "regard a metal not as an assembly of metal atoms, but rather as an array of positive metal ions held together by the attraction of intervening valence electrons." (Hume-Rothery, "The Structure of Metal and Alloys," page 17.) Or to put it differently, the crystal structure of metals may be looked upon as made up essentially of 2 interpenetrating lattices, one of positive metal ions, and the other exclusively of electrons.

These shared electrons, which are not the exclusive property of a particular atom, are responsible for many properties of the metal crystal other than its coherence and rigidity. Among these are such characteristic properties as electrical conductivity, thermionic emission, photoelectric phenomena, and a dozen or so thermo-magneto-electrical effects.

# New Types of D-C Transformers

By C. C. HERSKIND
ASSOCIATE AIEE

This paper presents 2 new types of d-c transformers using grid-controlled mercury-arc rectifiers. These transformers perform the same function on a d-c system as does the usual transformer on an a-c system. One type of d-c transformer which is discussed has a constant-current output characteristic, while the other has a constant-potential output. The theory of operation and operating characteristics are described and oscillograms taken on a small unit are shown.

## Introduction

FROM TIME to time various methods have been proposed for the purpose of transforming voltage on d-c systems without using a motor-generator set. Most of these schemes have employed some type of commutating device for interrupting the direct current; the interrupted current then being transformed by means of a transformer of the conventional type and finally again changed back into direct current by the commutating device. None of these schemes has proved practical, chiefly because of commutating difficulties with the interrupting device.

The use of thyratron tubes for the construction of a d-c transformer was proposed several years ago.[1] However, due in part to the limitations of the circuit then proposed, no applications have been made up to the present time.

This paper describes 2 new types of d-c transformers using grid-controlled mercury-arc rectifiers for commutating the direct current. The development of these d-c transformers is based upon a new circuit which was invented by Mr. C. A. Sabbah. This circuit operates upon an entirely new principle and possesses unique operating characteristics. It provides the commutating voltage, required for transferring current from winding to winding, which is essential to successful operation when using grid-controlled mercury-arc rectifiers. In addition, the circuit may also be used to change constant potential to constant current, as in the case of the constant-current d-c transformer.

The operation of the d-c transformer does not merely involve the conduction of current in succession through the several transformer windings. In order to accomplish this action, 2 requirements must be met, which influence directly the character of the circuit employed. These requirements are: First, magnetizing current must be supplied for exciting the core of the main transformer, and second, commutating voltage must be supplied for overcoming the counter electromotive forces which oppose the transfer of current from winding to winding. When grid-controlled mercury-arc rectifiers for commutating the current are used, further requirements must also be met; namely, sufficient commutating voltage must be supplied to provide a positive voltage on the anode, prior to conduction in order to obtain reliable pick-up, and to provide a negative voltage at the end of the conduction period for a sufficiently long time, in order to permit deionization of the anode; also the circuit action must be such that no attempt will be made to pass current through the circuit in the reverse direction during the anode conduction period.

Two types of d-c transformers, namely, the constant-current d-c transformer and the constant-potential d-c transformer, and their circuits and manner of operation, will be described. Oscillograms are included showing the wave forms obtained in actual operation.

## The Constant-Current D-C Transformer

The operation of the constant-current d-c transformer will be described first, inasmuch as it serves best to illustrate the principles of operation whereby the commutating voltage is obtained from the combination of 3-phase transformer and 3 capacitors.

The schematic connection diagram of the constant-current d-c transformer is shown on figure 1. The transformer consists of:

1. A 3-phase transformer having 2 coils per phase.
2. Three capacitors, one connected across each phase of the transformer.
3. Six mercury-arc rectifier tubes for commutating the current.
4. Two d-c reactors, one in the input and the other in the output circuit, for maintaining a smooth current wave.

In addition a source of a-c power is required for exciting the grids of the tubes. (A pilot motor-generator set driven from the d-c supply may be used.)

## Theory of Operation

The principle of operation may be best described by reference to the connection diagram figure 1, and the wave forms shown on figure 2. Referring to figure 2, let it be assumed that the grids of the primary and secondary anodes are excited from the pilot generator at a constant frequency, so that each secondary anode will fire before the primary anode on the corresponding leg of the transformer, by a time interval equal to $\alpha$ degrees. Then the primary and secondary anode current waves will be as shown by curves $a$ and $b$, since it is assumed that there is sufficient reactance in series with the 2 d-c circuits so that the d-c currents are constant.

A paper recommended for publication by the AIEE committee on electrical machinery. Manuscript submitted February 10, 1937; released for publication September 17, 1937.

C. C. HERSKIND is employed in the power rectifier engineering department of the General Electric Company, Schenectady, N. Y.

1. For numbered reference, see end of paper.

The capacitor current wave is fully determined if the primary and secondary anode current waves are known, as the capacitor must supply the current required to maintain the magnetomotive force in each transformer leg constant (neglecting magnetizing current). That this is the case will be evident if it is remembered that in a transformer, the primary and secondary ampere turns, neglecting magnetizing current, must be equal and opposite and that any current in a primary coil, which is not opposed by an equal and opposite current in the secondary coil, meets magnetizing reactance and generates a high voltage. Of course, there is no unidirectional component of current in the usual transformer, but this will not alter the validity of this requirement. The above principle is highly important, as the whole theory of operation of the constant-current d-c transformer is based upon the fact that the transformer magnetomotive force (neglecting magnetizing current) is maintained constant.

The average magnetomotive force in each transformer leg, during the whole cycle, is equal to the average of the magnetomotive forces due to the primary and secondary anode currents, each averaged over the cycle. In order to maintain this constant value of magnetomotive force on the transformer leg, the capacitor current must have the wave form shown by curve *c* on figure 2. The capacitor voltage wave is shown on curve *d*. The voltage is readily determined from the capacitor current as the current is constant during each interval.

The input and output voltages, curves *e* and *f*, are found by taking the capacitor voltages during the interval that the anode is conducting. The voltage will be supplied by any one phase only during the time that its anode is conducting. When the anode is not conducting, the voltage will be supplied from the other phases. The ripple in the d-c voltage wave is absorbed by the reactors in series with the 2 d-c lines. A clearer conception of the physical processes involved may be obtained if it is noted that during the interval $t_1$ to $t_2$, capacitor 1 is discharging into the output circuit. Its voltage falls as the secondary anode continues firing, until the secondary anode on the second phase is permitted to fire (by grid control), and the current transfers from anode 1′ to anode 2′, as capacitor 2 has a higher voltage than capacitor 1, and in the proper direction to force commutation. At $t_2$, the capacitor 1 is practically discharged, but now the primary anode on phase 1 is firing, and it is again being charged from the input circuit. At the end of the charging period, anode 2 is permitted to fire, and the input current is transferred from anode 1 to anode 2, as capacitor 2 has a lower counter electromotive force voltage than 1. During the period when neither primary nor secondary anode on phase 1 are firing, capacitor 1 discharges into the transformer winding, in order to maintain the required leg magnetomotive force,

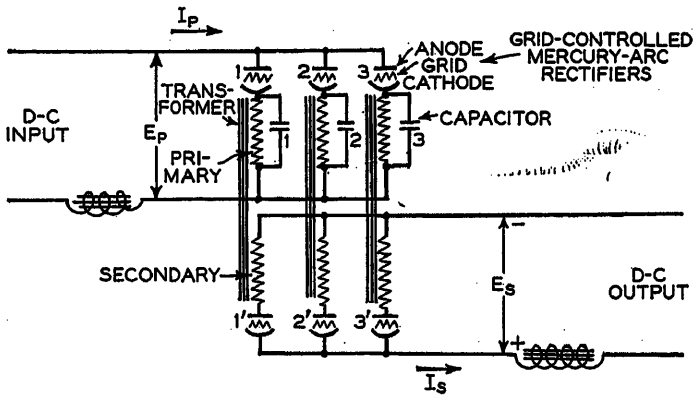

**Figure 1. Connection diagram of constant-current d-c transformer**

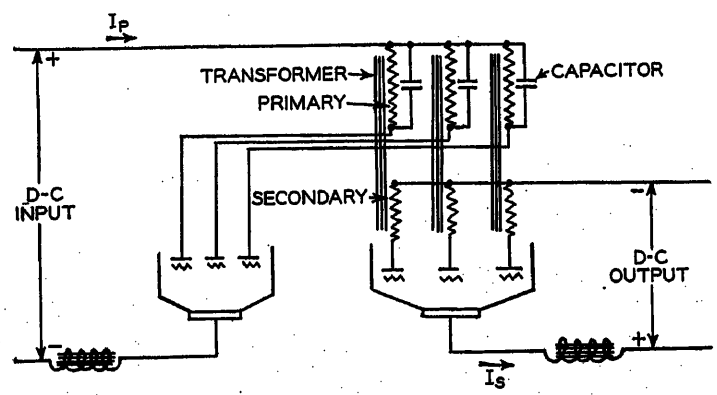

**Figure 1a. D-c transformer using 2 3-anode metal-tank grid-controlled mercury-arc rectifiers**

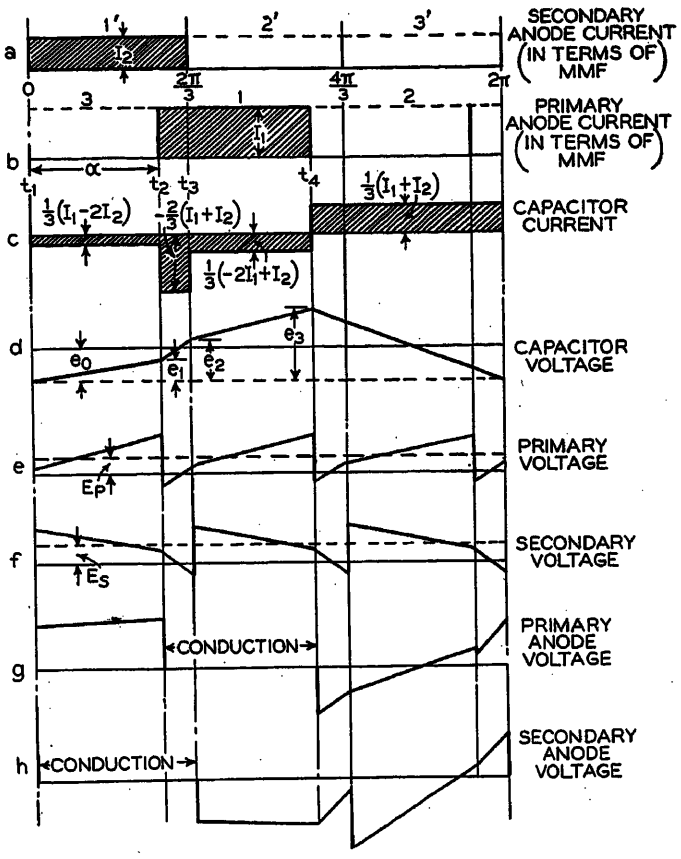

**Figure 2. Constant-current d-c transformer wave forms. Case I—$\alpha >$ 0 degrees and $<$ 120 degrees**

and reverses its polarity, so that it has the correct polarity to supply power to the output circuit, when it is again permitted to fire.

The anode voltages during the period when the anode is not conducting (that is, the anode-to-cathode voltages) may also be found from the capacitor voltages. They are shown by curves *g* and *h*. From curve *g* it will be noted that the primary anode operates essentially as an inverter, the anode having a negative voltage for a short time during the first part of the idle period, and then a positive voltage during the rest of the period. Also, from curve *h*, the secondary anode will be seen to operate essentially as a rectifier, having a negative voltage during most of the idle period and becoming positive shortly before conduction. In other words, the constant current d-c transformer is a unique combination of inverter and rectifier, which supplies its own commutating requirements.

## Voltage Relations

The voltage and current relations between the input and output sides of the constant-current d-c transformer may be readily derived if the capacitor current and voltage waves are determined by assuming various values of primary and secondary current. Referring to figures 1 and 2, let

$I_p$ = primary d-c current input
$I_s$ = secondary d-c current output
$n$ = ratio pri-sec turns on transformer
$f$ = frequency of grid excitation (supplied by pilot generator)
$\alpha$ = angle of retard of primary anodes with respect to secondary anodes (degrees)

$$k = \frac{\alpha}{120^\circ}$$

The average d-c component of the magnetomotive force on each leg of the transformer due to the anode currents is $^1/_3(I_1 + I_2)$, where $I_1$ is the magnetomotive force due to primary anode current $I_p$ flowing in primary winding, that is, $I_1 = I_p$ times the number of primary turns, and $I_2$ is the magnetomotive force due to secondary anode current $I_s$ flowing in secondary winding, that is, $I_2 = I_s$ times the number of secondary turns $= (I_s/n)$ times the number of primary turns. For simplicity the magnetomotive force may be expressed in terms of primary current, that is, $I_1 = I_p$ and $I_2 = I_s/n$.

In order to maintain the magnetomotive force on the transformer leg constant, the capacitor currents during the successive intervals will have the values indicated on curve *c* of figure 2.

Inasmuch as the capacitor current is constant during each interval due to the smoothing reactors in the input and output circuits, (if transformer magnetizing current is neglected) the capacitor voltage wave is of trapezoidal form during any interval and the change in capacitor voltage during any interval is

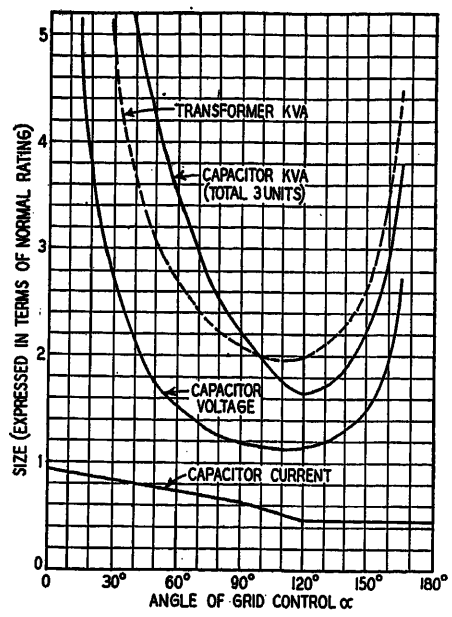

**Figure 4. Size of capacitors and transformer**

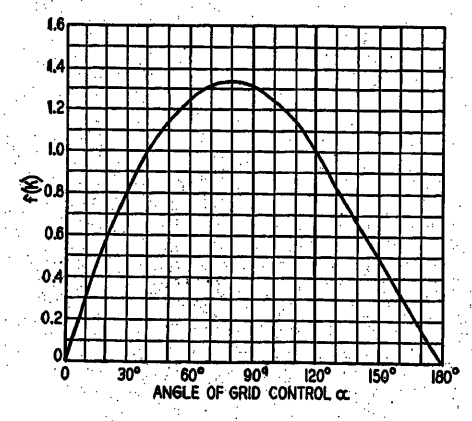

**Figure 3. Value of functions $(4K - 3K^2)$ and $(3 - 2K)$**

$$e = \int \frac{idt}{c} = \frac{it}{cf}$$

where

$t$ = duration of the interval expressed as a fraction of one cycle
$c$ = capacity of one capacitor
$i$ = capacitor current
$f$ = frequency of grid excitation

CASE I

If it is assumed that the conducting periods of the primary and secondary anodes connected to the same leg overlap, that is, if $\alpha$ is greater than zero and less than 120 degrees, the capacitor voltages indicated on figure 2 curve *d* will be:

$$e_1 = \frac{1}{9cf}[-I_1k + 2I_2k] \quad (1)$$

$$e_2 = \frac{1}{9cf}[2I_1 + 2I_2 - 3I_1k] \quad (2)$$

$$e_3 = \frac{1}{9cf}[2I_1 + 2I_2 - I_1k - I_2k] \quad (3)$$

Since the capacitor current wave must be such that $\int edt$ over the cycle is zero, it follows that

$$e_0 = \frac{1}{9cf}[I_1 + I_2 - I_1k] \quad (4)$$

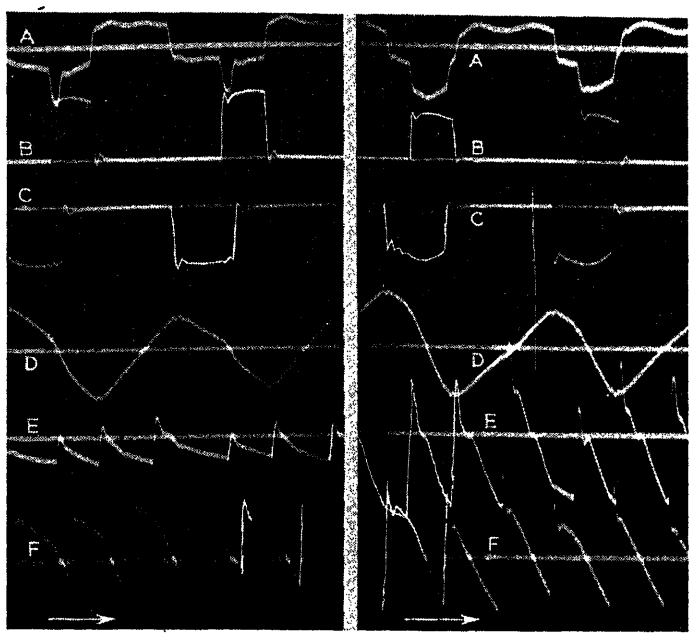

**Figure 5. Oscillograms showing constant-current d-c transformer current and voltage wave forms**

Curve *A*—Capacitor current
Curve *B*—Primary anode current
Curve *C*—Secondary anode current
Curve *D*—Capacitor voltage
Curve *E*—D-c input voltage
Curve *F*—D-c output voltage

The average value of both the input and output voltages may readily be calculated from these capacitor voltages. The average input voltage is then

$$E_p = \frac{1}{18\ cf}\,[4k - 3k^2]\,I_2 = \frac{1}{18cf}\,[4k - 3k^2]\,\frac{I_s}{n} \qquad (5)$$

and the average output voltage is

$$E_s = \frac{1}{18\ cf}\,[4k - 3k^2]\,I_1 = \frac{1}{18\ cf}\,[4k - 3k^2]\,\frac{I_p}{n} \qquad (6)$$

CASE II

Similar expressions may be derived for the case where the conducting periods of the primary and secondary anodes do not overlap, that is, $\alpha$ is greater than 120 degrees and less than 180 degrees. The equations for the average input and output voltages when the anodes do not overlap, are, respectively,

$$E_p = \frac{1}{18\ cf}\,[3 - 2K]\,\frac{I_s}{n} \qquad (7)$$

and

$$E_s = \frac{1}{18\ cf}\,[3 - 2K]\,\frac{I_p}{n} \qquad (8)$$

These equations establish the voltage relations required for constant-potential-to-constant-current transformation. From the above expressions it will be noted that the relation between the voltage input and the current output may be changed in four ways, namely; first, by changing the grid phase angle between primary and secondary anodes; second, by changing the frequency; third, by changing the capacity; and fourth, by changing the transformer turn ratio between primary and secondary coils.

The constant-current d-c transformer may be operated with any angle of grid retard of the primary anodes with respect to the secondary anodes between the values zero and 180 degrees. The relation between the primary voltage and secondary current, as the angle of grid retard varies, is expressed by the functions $(4k - 3k^2)$ and $(3 - 2k)$, which are shown graphically on figure 3; with angles of grid retard at or near zero and 180 degrees, the secondary current becomes very large and is close to infinity for all values of impressed voltage. The characteristics of the transformer-capacitor combination under these conditions will be described in connection with the constant potential d-c transformer.

The effective values of the voltage and current appearing on the capacitors and transformer may be calculated from the relations indicated on figure 2, and the voltage equations (1), (2), (3), and (4). The calculated sizes of the capacitors and transformer for various angles of grid retard are shown on figure 4.

In the d-c transformer circuit, shown on figure 1, there exists a d-c component of magnetomotive force on each leg of the transformer core. This is apparent when it is

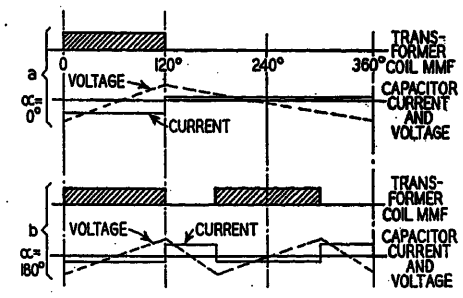

**Figure 6. Commutation transformer wave forms**

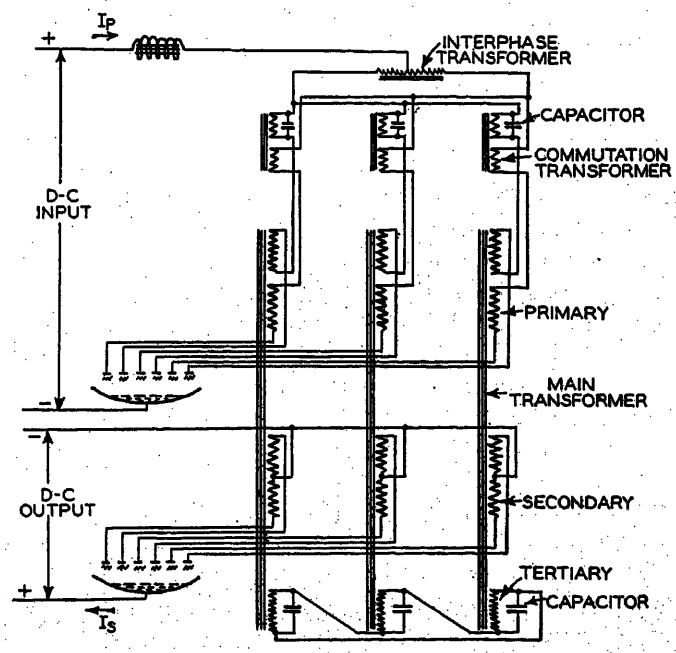

**Figure 7. Connection diagram of constant-potential d-c transformer**

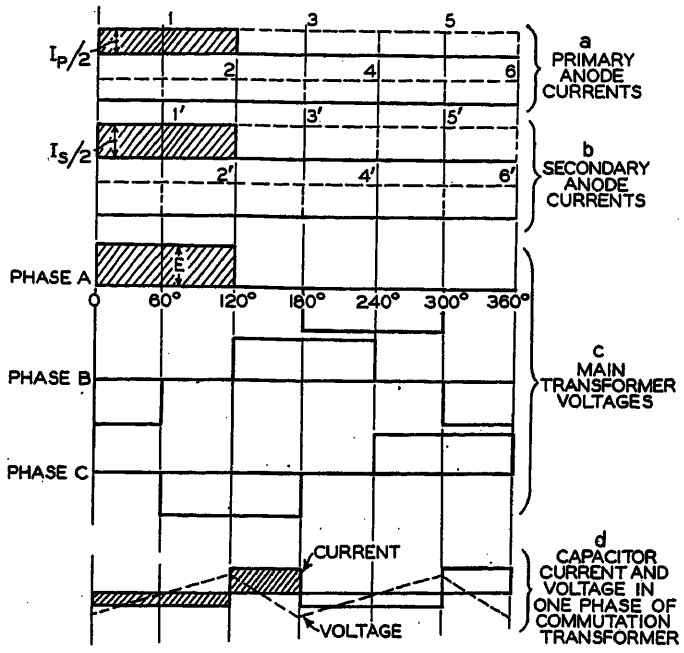

**Figure 8. Constant-potential d-c transformer wave forms**

noted that all currents entering the unit from the input side and leaving on the output side flow through the transformer coils in the same direction. This d-c component may be eliminated without altering the action of the transformer, by suitably zig-zagging the transformer coils.

## Test Results

A constant-current d-c transformer of approximately 40-kw capacity has been tested in the factory. The tests were made with the d-c transformer connected to a constant-voltage source and the output current was used to drive a d-c motor. The output current was controlled by varying the frequency applied to the grids (speed control on pilot motor-generator set). The high output current required to start the motor was obtained by operating the transformer at a high grid frequency. As the motor came up to speed, the grid frequency was reduced. The motor was held at any desired speed by varying the frequency of the grid control. On another test, the d-c transformer connections were reversed and it was forced to pump power back into the supply, that is, to regenerate.

The constant-current relationship has been proved by these tests. Figures 5*a* and 5*b* are oscillograms of voltages and currents in various parts of the circuit. The close agreement between the theoretical wave form, shown on figure 2, and the actual wave form, as determined by test, should be noted.

## The Constant-Potential D-C Transformer

For many applications, the constant-current characteristic is not suitable, and a d-c transformer having a constant-potential characteristic is required. A constant-potential d-c transformer may be constructed by making use of the transformer and capacitor combination, which has already been described in connection with the constant-current d-c transformer. In the case of the constant-potential transformer the transformer and capacitor combination is used to provide a commutating voltage and it will be referred to hereafter as the commutation transformer.

The commutation transformer consists of the transformer and capacitor combination used in the constant-current d-c transformer, with the angle of grid control between primary and secondary winding adjusted for either zero or 180 degrees. The capacitor current and voltage relations with angle of control equal to zero or 180 degrees are shown on figure 6. It should be noted that the capacitor voltage is directly proportional to the load current, so that the commutation transformer will furnish the required voltage at all loads to overcome the reactive voltages opposing transfer from winding to winding since these reactive voltages are proportional to the load.

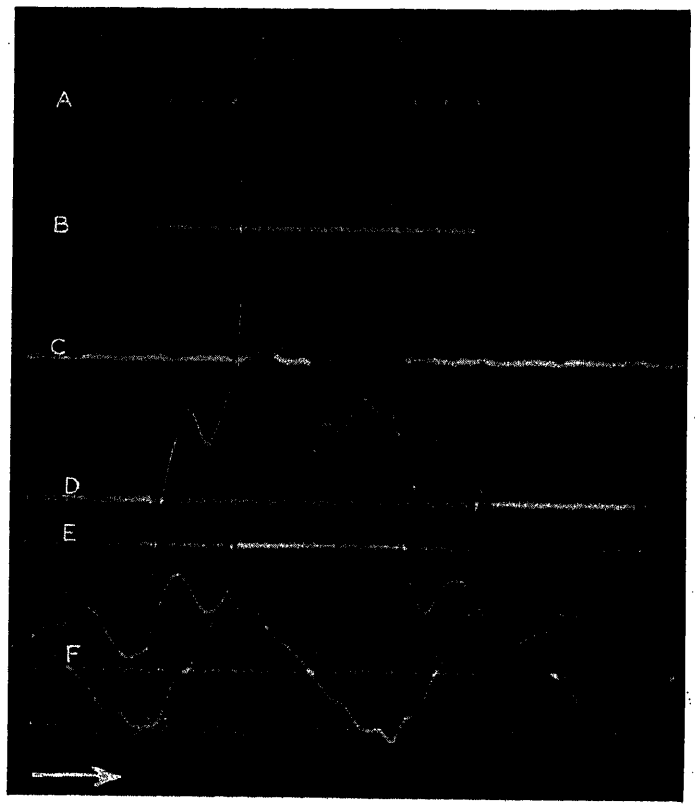

**Figure 9. Oscillogram showing constant-potential d-c transformer current and voltage wave forms**

Curve *A*—Main transformer primary-coil voltage
Curve *B*—Primary anode current
Curve *C*—Secondary anode current
Curve *D*—Primary anode-to-cathode voltage
Curve *E*—Secondary anode-to-cathode voltage
Curve *F*—Commutating-transformer coil voltage

The schematic connection diagram of the constant-potential d-c transformer is shown on figure 7. Referring to this diagram, the constant-potential d-c transformer

consists of (1) a 3-phase main transformer, having 2 primary coils, 2 secondary coils, and tertiary coil on each phase; (2) a commutation transformer having a 3-legged core with 2 coils per phase; (3) 3 capacitors, one connected across each phase of the commutation transformer; (4) an interphase transformer; (5) 3 capacitors, one connected across each tertiary coil on the main transformer; (6) 2 6-anode grid-controlled mercury-arc rectifiers, one connected to the primary windings of the main transformer and the other connected to the secondary windings of the main transformer.

The constant-potential d-c transformer consists essentially of a 6-anode inverter supplying power to the primary windings of the main transformer, and a 6-anode rectifier, receiving power from the secondary windings of the main transformer. The commutating voltage for transferring current from anode to anode on the inverter is supplied by the commutation transformer. The inverter is caused to operate as 2 3-anode circuits by means of the interphase transformer. The magnetizing current

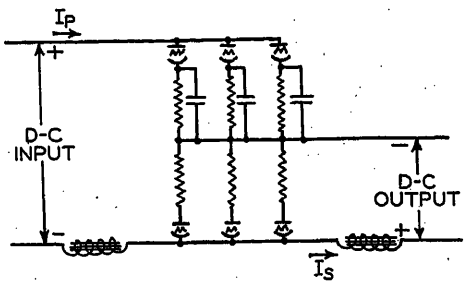

**Figure 10. Diagram showing alternative connections for constant-current d-c transformer**

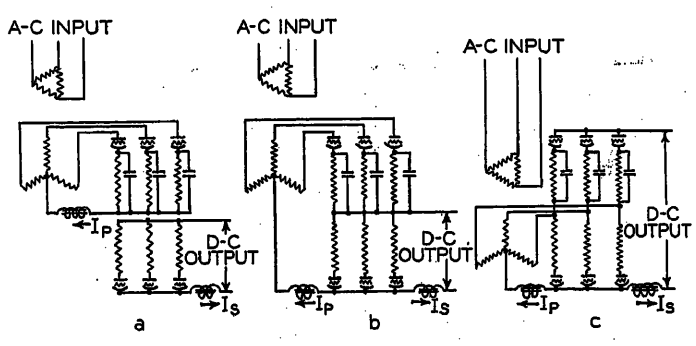

**Figure 11. Circuits for changing constant-potential alternating current to constant-current direct current (single frequency)**

for the main transformer is supplied by the capacitors connected across the tertiary windings of the main transformer.

The operation of the constant-potential d-c transformer will best be understood by referring to figure 8, which shows the wave form in the d-c transformer circuit. On figure 8 curves *a* and *b* show the primary anode current and secondary anode-current wave forms, respectively. It will be noted that each anode carries current for approximately 120 degrees. Curve *c* shows the transformer coil voltages on the different phases of the main transformer. Curve *d* shows the voltage supplied by the commutation transformer for effecting the transfer of current from anode to anode, and permitting deionization of the main anode, following the conduction period.

The voltage ratio of the constant-potential d-c transformer is determined by the winding ratio between primary and secondary coils on the main transformer. This voltage ratio is not susceptible to control by means of the grids, as in the case of the constant-current d-c transformer, and no control grids are required on the output rectifier.

## Test Results

A constant-potential d-c transformer has been set up and tested in the factory, drawing power from a 500-volt d-c shop system, and driving a 250-volt d-c motor. The constant-potential d-c transformer was found to have a shunt voltage characteristic similar to that of an ordinary rectifier.

Figure 9 shows an oscillogram of the voltage and current in various parts of the constant-potential d-c transformer circuit.

## Other Arrangements and Applications

Various arrangements of the combination of 3-phase transformer and 3 capacitors forming the constant-current d-c transformer are possible. Figure 10 shows an alternative method of connecting the input side of the constant-current d-c transformer. This connection has been shown to have the same constant-current characteristic as that of figure 1.

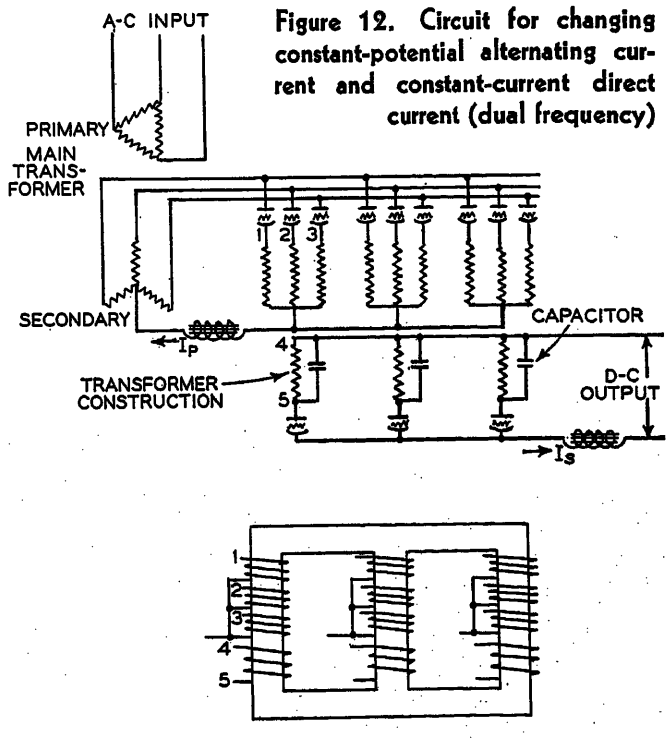

**Figure 12. Circuit for changing constant-potential alternating current and constant-current direct current (dual frequency)**

The constant-current d-c transformer circuit can also be used for changing constant-potential alternating current

to constant-current direct current, that is, as a constant-current rectifier. Figure 11 shows 3 similar circuits of this type. In these circuits, the grids are excited at the same frequency as that of the a-c system. Figure 12 shows a circuit for changing constant-potential alternating current to constant-current direct current, in which the grids may be excited at a different frequency than that of the a-c system. The circuits shown in figures 11 and 12 may also be operated as inverters, that is, either changing constant-potential direct current to constant-current alternating current or changing constant-current direct current to constant-potential alternating current.

## Conclusions

The general circuit and principles of operation which are described in this paper in connection with the constant-potential and constant-current d-c transformers, may also be applied to other rectifier circuits. Various arrangements of this general circuit utilizing a 3-phase transformer and 3 capacitors in combination with rectifier tubes, are possible. The new principles which have been described will undoubtedly prove useful in the development of apparatus for various rectifier applications, particularly those involving inverter operation.

# Workers in New Chicago Building to Breathe Electrically Cleaned Air

THAT MANY PEOPLE are interested in air conditioning and its allied processes was evidenced by the wide discussion of a paper on "A New Electrostatic Precipitator" by G. W. Penney (A'26) at the 1937 winter convention (ELECTRICAL ENGINEERING, volume 56, January 1937, pages 159–63). That the principle of electrostatic cleansing of air has a large-scale practical use now has been demonstrated by the use of this method in cleaning the entire air supply of the first 4 floors and lower arcade of the new Field Building in Chicago, Ill. Located in Chicago's downtown loop area, where annually the dirt deposited from the atmosphere is said to average 1,000 tons per square mile, the precipitators in this building supply more than 16 million cubic feet of cleaned air per hour.

Dust particles so small that they pass through any ordinary mechanical filter are readily removed by means of electrostatic precipitation. By this process impurities are taken from the air not by sifting them out mechanically, but by charging the particles electrically and withdrawing them as they pass through an electrostatic field. The air is first ionized by passing it through a maze of grounded cylinders and fine wires; the wires, charged to a negative potential of 12,000 volts, are only 0.005 inch in diameter and of course cannot be seen in the photograph of the intake side of one of the Field Building precipitators shown on this page. After the solid particles have been charged, the treated air next is drawn through a series of cells consisting of alternately spaced high-potential and grounded plates, the charged particles of impurities adhere to the plates, and the air so freed of solid matter passes on through ducts that lead to the areas being served by the equipment. Each cell of the Chicago system contains 111 plates 8 by 9 inches in size, and nearly half a mile of the fine tungsten ionizing wire was used in the construction of the 369 cells. The high-potential precipitator plates are charged to a positive potential of 5,000 volts.

Particles having diameters smaller than 0.0025 inch pass readily through 200-mesh screens of mechanical filters. These particles ordinarily are invisible, except in

rays of bright light, but are extremely coarse in comparison with the atmospheric dust particles that fill the air of a busy city. The average solid particle in cigarette smoke has a diameter of only 0.0000039 inch. Enlarged 250,000 times, the larger particles that pass through a 200-mesh screen would be 50 feet in diameter; an average atmospheric dust particle would appear as big as a baseball; but at the same magnification the average cigarette-smoke particle would be a little more than an inch in diameter, or slightly smaller than a golf ball.

# Load Loci for Transformers in Parallel

By ANATOLI C. SELETZKY
MEMBER AIEE

## Abstract

The method of circular loci is applied to the problem of 2 transformers operating in parallel. It is shown that with comparatively little computation the variation of current in either transformer or the ratio of the 2 currents may be obtained as a function of the load impedance or the ratio of transformation. A numerical problem is given to illustrate a typical application.

## Introduction

THE OPERATION of 2 transformers in parallel under ideal conditions assumes equal percentage resistances and reactances and equality of high-tension and low-tension voltages, neglecting excitation currents. Frequently it is necessary to connect in parallel transformers which do not conform to the ideal requirements. It is then necessary to change the ratio of transformation of one of the transformers to prevent overloading. The problem of parallel operation of transformers has been treated by many investigators, references to several being given at the end of this paper.[1–5]

When confronted simultaneously with several variables, involved in parallel operation, such as load impedance, load power factor, tap position and internal impedance, the author has found the method of circular loci to be convenient and time saving for determining the variation of transformer currents as a function of any of the variables present. This method is the only alternative to the laborious and time-consuming point-by-point solution of expressions with complex coefficients.

This paper develops the application of circular loci to the determination of currents and current ratios for the general case of 2 transformers connected in parallel. It is shown how, with comparatively little computation, a circular locus may be plotted which gives directly the magnitude and phase angle of the desired unknown as the variable passes through its complete range, from minus infinity or zero to plus infinity.

A paper recommended for publication by the AIEE committee on power transmission and distribution. Manuscript submitted July 12, 1937; released for publication September 21, 1937.

ANATOLI C. SELETZKY is assistant professor of electrical engineering at Case School of Applied Science, Cleveland, Ohio.

## General Equations for Parallel Operation

In figure 1 are shown 2 transformers, numbered 1 and 2, respectively, connected in parallel and supplying a load $Z_L$. The equivalent circuits of the transformers are assumed to be reduced to the low-tension side. The exciting admittances are considered to be negligible and the elements of the circuits are assumed to be linear. The load impedance, $Z_L$, may have any phase angle and its magnitude may vary from short circuit to open circuit. The following symbols will be used throughout the paper:

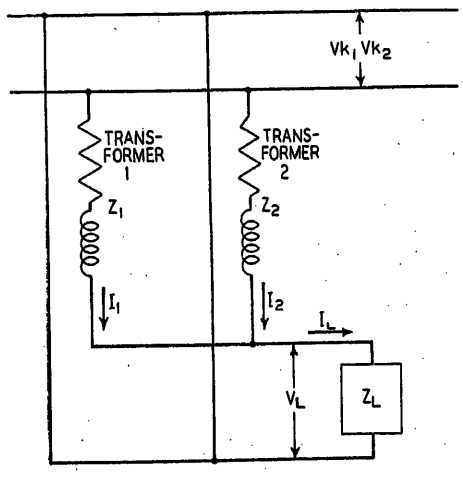

**Figure 1**

$I_1$ = current in low-tension winding of transformer 1
$I_2$ = current in low-tension winding of transformer 2
$I_L$ = load current in low-tension side
$Z_1$ = equivalent impedance of transformer 1 referred to low-tension side
$Z_2$ = equivalent impedance of transformer 2 referred to low-tension side
$V$ = terminal voltage on high-tension side
$V_L$ = terminal voltage on low-tension side
$k_1$ = ratio of transformation of transformer 1
$k_2$ = ratio of transformation of transformer 2

$$\text{ratio of transformation} = \frac{\text{induced voltage in low-tension winding}}{\text{induced voltage in high-tension winding}}$$

The problem to be considered is the behavior of the individual transformer currents, $I_1$ and $I_2$, as $Z_L$ varies and the transformer ratios, $k_1$ and $k_2$, remain constant; also the variation of transformer currents when $Z_L$ is fixed and one of the ratios, $k_1$ or $k_2$, varies.

Writing the voltage drops in the 2 circuits

$$V_L = Vk_1 - I_1Z_1 = Vk_2 - I_2Z_2$$

and eliminating the load voltage and current by the relationships:

$$I_L = \frac{V_L}{Z_L} \text{ and } I_L = I_1 + I_2$$

the equations may be solved for $I_1$ and $I_2$ giving

$$I_1 = V\frac{k_1Z_2 + (k_1 - k_2)Z_L}{Z_1Z_2 + (Z_1 + Z_2)Z_L} \quad (1)$$

$$I_2 = V\frac{k_2Z_1 - (k_1 - k_2)Z_L}{Z_1Z_2 + (Z_1 + Z_2)Z_L} \quad (2)$$

Both expressions for current are linear in numerator and denominator with respect to all the circuit constants $Z_1$, $Z_2$, $Z_L$, $k_1$, and $k_2$.

The canonical form of a circle, written as a linear fractional transformation is

$$S = \frac{\alpha + \beta\rho}{\gamma + \delta\rho} \tag{3}$$

Here $S$ is a vector whose extremity follows a circle as the scalar variable $\rho$ varies from minus to plus infinity and $\alpha$, $\beta$,$\gamma$,$\delta$ are complex constants.[6]

It is evident that the transformer currents follow circular loci when any one of the circuit constants be considered as the variable, because in each case both numerator and denominator can be written in the form of a constant term plus a constant times the variable scalar, giving thereby the equation of a circle.

That the transformer currents follow circular loci could also have been realized immediately from the theorem of circularity for a general network which states: "that in a network containing any number of linear and bilateral self- and mutual-impedance elements connected in any manner, with constant sinusoidal electromotive forces of like frequency connected in any arm, all currents and all voltages follow circular loci when any one impedance is varied along a straight line in the complex plane."[7] Thus, if any one of the circuit impedances be considered to vary at constant power-factor both transformer currents will follow circular loci.

## Loci of $I_1$ and $I_2$ With Variable $Z_L$

With the load impedance $Z_L$ assumed to be the variable the equation for $I_1$ is written as

$$I_1 = V\frac{k_1Z_2 + (k_1 - k_2)1\angle\theta_L \mid Z_L \mid}{Z_1Z_2 + (Z_1 + Z_2)1\angle\theta_L \mid Z_L \mid} \tag{4}$$

Here the variable $Z_L$ has been put in the form

$$Z_L = \mid Z_L \mid e^{j\theta_L} = 1\angle\theta_L \mid Z_L \mid \tag{5}$$

where $\theta_L$ is the phase angle of $Z_L$ and $|Z_L|$is the magnitude of $Z_L$. In this way the scalar variable $\rho$ of the canonical form becomes $|Z_L|$and the phase angle of $Z_L$ becomes part of the complex constant $\delta$.

The constants of the canonical form for $I_1$ are then:

$$\left.\begin{aligned} \alpha &= Vk_1Z_2 & \gamma &= Z_1Z_2 \\ \beta &= V(k_1 - k_2)1\angle\theta_L & \delta &= (Z_1 + Z_2)1\angle\theta_L \\ \rho &= \mid Z_L \mid \end{aligned}\right\} \tag{6}$$

The invariant points, that is the values of $I_1$ for $|Z_L| = 0$ and $|Z_L| = \infty$ are

$$\left.\begin{aligned} I_{1(0)} &= V\frac{k_1}{Z_1} \quad \text{(short circuit)} \\ I_{1(\infty)} &= V\frac{k_1 - k_2}{Z_1 + Z_2} \quad \text{(open circuit)} \end{aligned}\right\} \tag{7}$$

In the same manner the current in transformer 2 is written as

$$I_2 = V\frac{k_2Z_1 - (k_1 - k_2)1\angle\theta_L \mid Z_L \mid}{Z_1Z_2 + (Z_1 + Z_2)1\angle\theta_L \mid Z_L \mid} \tag{8}$$

The constants in this case are:

$$\left.\begin{aligned} \alpha &= Vk_2Z_1 & \gamma &= Z_1Z_2 \\ \beta &= -V(k_1 - k_2)1\angle\theta_L & \delta &= (Z_1 + Z_2)1\angle\theta_L \\ \rho &= \mid Z_L \mid \end{aligned}\right\} \tag{9}$$

The invariant points are:

$$\left.\begin{aligned} I_{2(0)} &= V\frac{k_2}{Z_2} \quad \text{(short circuit)} \\ I_{2(\infty)} &= -V\frac{k_1 - k_2}{Z_1 + Z_2} \quad \text{(open circuit)} \end{aligned}\right\} \tag{10}$$

The internal impedances $Z_1$ and $Z_2$ used in the equations should correspond to the particular transformer ratios $k_1$ and $k_2$ associated with them. In certain problems it is desired to study load sharing when either ratio $k_1$ or $k_2$ is changed. For a theoretically correct solution of such a problem it would be necessary to know the variation of internal impedance corresponding to each tap on the transformer. If such data are available, the proper values of $Z_1$ and $Z_2$ appropriate to the particular tap positions being used should be employed in the equations.

If the problem involves small changes in ratio from the one pertaining to the value of internal impedance used in the equations, it is frequently permissable, for the degree of accuracy desired in the results, to consider the internal impedance a constant as the ratio is changed slightly.

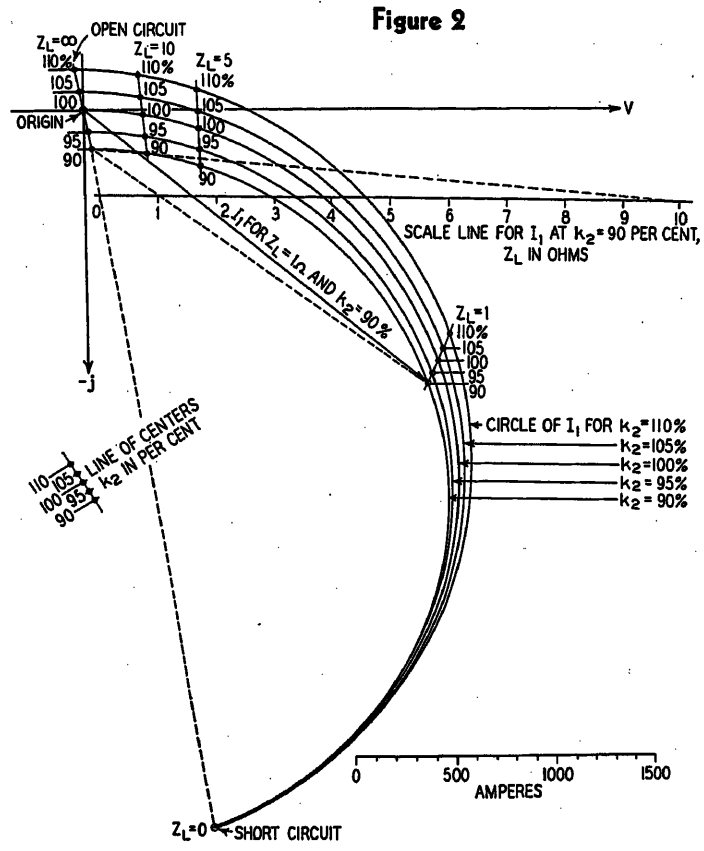
With this assumption the construction of a family of circles, considering the transformation ratio $k_1$ or $k_2$ as the parameter, is greatly simplified. The ratios $k_1$ and $k_2$ occur only in the numerators of the expressions for transformer currents. If, for the moment, the load impedance $Z_L$ and one of the ratios, as $k_1$ be assumed fixed, and the ratio $k_2$ be assumed as the variable, the currents $I_1$ and $I_2$ will follow straight lines. For example, the current $I_1$ in equation 1 may be expressed as

$$I_1 = \frac{Vk_1(Z_2 + Z_L)}{Z_1Z_2 + (Z_1 + Z_2)Z_L} - k_2\frac{VZ_L}{Z_1Z_2 + (Z_1 + Z_2)Z_L} \tag{11}$$

which is of the form $\alpha + k_2\beta$.

This is a straight line with a linear scale in $k_2$, passing through the point $\alpha$ with an angle equal to the argument of $\beta$.

Similarly the current $I_2$ in equation 2 may be regarded under the same conditions as



$$I_2 = \frac{-Vk_1Z_L}{Z_1Z_2 + (Z_1 + Z_2)Z_L} + k_2\frac{V(Z_1 + Z_L)}{Z_1Z_2 + (Z_1 + Z_2)Z_L} \tag{12}$$

This is another straight line. In the same manner the 2 equations for currents may be regrouped with respect to $k_1$ as the variable. These straight-line relationships facilitate the plotting of a family of circles with either transformer ratio as the parameter and the load impedance as the variable. For instance, 2 circles are drawn with the load impedance as the variable for 2 different values of $k_2$. Points on these circles for equal values of $Z_L$ are then connected by straight lines. The interval of $k_2$ between such pairs of corresponding points may then be used as a scale of $k_2$ to spot points on circles for other values of $k_2$.

The vector to the center of a circle is[6]

$$C = \frac{\alpha\bar{\delta} - \beta\bar{\gamma}}{\gamma\bar{\delta} - \delta\bar{\gamma}} \tag{13}$$

**Figure 2**

in which the vinculum (−) indicates the conjungate of the vector to which it is attached.

Substituting the constants given in equations 6 the center vector $C_1$ to the center of the circle for $I_1$ is

$$C_1 = j\frac{V}{Q}\left[k_1 Z_2(\overline{Z_1 + Z_2})1\angle -\theta_L - (k_1 - k_2)1\angle\theta_L(\overline{Z_1 Z_2})\right] \quad (14)$$

where

$$\left.\begin{aligned} Q &= 2(R'X'' - R''X') \\ Z_1 Z_2 &= R' + jX' \\ (Z_1 + Z_2)1\angle\theta_L &= R'' + jX'' \end{aligned}\right\} \quad (15)$$

Similarly the center vector $C_2$ to the center of the circular locus of $I_2$ becomes

$$C_2 = j\frac{V}{Q}\left[k_2 Z_1(\overline{Z_1 + Z_2})1\angle -\theta_L + (k_1 - k_2)1\angle\theta_L(\overline{Z_1 Z_2})\right] \quad (16)$$

It should be noted that both center vectors $C_1$ and $C_2$ are linear functions of $k_1$ and $k_2$. Thus if the families of circles for $I_1$ and $I_2$ are drawn with $Z_L$ as the variable and either $k_1$ or $k_2$ as the parameter, the centers of the circles for both families will lie on straight lines whose equations are $C_1$ and $C_2$, respectively. Furthermore the distances between the centers of the circles will be proportional to the increments of the parameter $k_1$ or $k_2$.

The radius of a circle is given by the expression[6]

$$R = \left|\frac{\alpha\delta - \beta\gamma}{\bar{\delta}\gamma - \gamma\bar{\delta}}\right| \quad (17)$$

Substituting the transformer constants into the above equation, the radius $R_1$ for the locus of $I_1$ is

$$R_1 = \left|\frac{VZ_2}{Q}\left[Z_1(k_1 - k_2) - k_1(Z_1 + Z_2)\right]\right| \quad (18)$$

Similarly the radius $R_2$ for the locus of $I_2$ is

$$R_2 = \left|\frac{VZ_1}{Q}\left[Z_2(k_1 - k_2) + k_2(Z_1 + Z_2)\right]\right| \quad (19)$$

The expressions for the 2 radii $R_1$ and $R_2$ are likewise linear with respect to $k_1$ and $k_2$. Thus if the radii of 2 circles for different values of transformer ratio are known, the difference between these 2 radii may be used as a linear scale for obtaining radii for other values of transformer ratio.

Hence, to obtain a plot of a family of circles of transformer current with variable load impedance and one of the transformer ratios as the parameter, it is necessary to employ the analytical expression for only 2 of the circles; the linear relationships between corresponding points on different circles and between the centers of the circles suffice to locate other circles and points thereon, for any desired values of $k_1$ or $k_2$.

A circular locus may be determined by calculating 3 points on its periphery from the analytical expression or by computing the center vector and the radius. The 3-point method generally involves less computation because 2 of the points used for location are the invariant points which reduce the expression from the quotient of the sums of 2 complex terms to a quotient of 2 complex terms only. For the third point any convenient value of $Z_L$ may be chosen. In this manner the entire analytical expression need be used only once, namely, for the calculation of the third point.

The third point is also used in conjunction with the invariant points for the determination of the linear scale line. This scale line is any line drawn perpendicular to the line joining the center of the circle and the point on the circle corresponding to $I_{1(\infty)}$, the open-circuit point. The intersections of the scale line, drawn in this manner, with lines joining points on the circle at which $Z_L$ is known and the open-circuit point, determine a linear scale of $Z_L$ on the scale line. Any chord then drawn through the open-circuit point and intersecting the scale line, connects corresponding points of $Z_L$ on the scale line and on the circle.

If, for example, it is desired to plot a family of circles of $I_1$ with the ratio of the transformer 2, $k_2$, as the parameter, the 3-point method is employed to locate 2 circles for 2 different values of $k_2$. The center vectors and the radii of these circles may be computed to check the results. Scale lines are then drawn for both circles and as many points of $I_1$ as desired are spotted on the 2 circles. Corresponding points of $I_1$ (for equal values of $Z_L$) are then joined with straight lines. The intervals on the connecting lines are then linearly subdivided to form a convenient scale of $k_2$. These scales are then projected at both ends of the connecting lines, thereby giving points on other circles for the same values of $Z_L$. A straight line through the centers of the 2 circles is similarly subdivided and extended with a scale of $k_2$ thus locating the center points of circles for other values of $k_2$.

With $k_2$ as the parameter of the $I_1$ circles, the short-circuit point $L\,I_{1(0)} = Vk_1/Z_1$ is common to all the circles and the open-circuit point follows the straight line,

$$I_{1(\infty)} = V\frac{k_1 - k_2}{Z_1 + Z_2}$$

A family of $I_2$ circles with either transformer ratio as the parameter is constructed similarly. It should be observed that if $k_2$ be taken as the parameter, $k_2$ occurring in both invariant points of $I_2$ (see equation 10), the short-circuit point follows the line $I_{2(0)} = Vk_2/Z_2$ and the open-circuit point follows the line

$$I_{2(\infty)} = -V\frac{k_1 - k_2}{Z_1 + Z_2}$$

Although any values of $k_1$ or $k_2$ may be used to obtain a family of $I_1$ and $I_2$ circles, it should be remembered that the circles used for final results should not pertain to values of $k_1$ or $k_2$ far enough away from the values of these ratios which apply to the internal impedances used in the parametric expressions of the circles, to vitiate the approximation that the internal impedances remain constant. Otherwise it is not possible to draw a family of curves as described above and a separate expression must be set up for each circle with values of $Z_1$ and $Z_2$ corresponding to the particular values of $k_1$ and $k_2$ desired.

If the expressions for $I_1$ and $I_2$, equations 1 and 2, be divided one by the other, a convenient relationship for the ratio of load currents $I_1/I_2$ results. This is

$$\frac{I_1}{I_2} = \frac{k_1Z_2 + (k_1 - k_2)Z_L}{k_2Z_1 - (k_1 - k_2)Z_L} \tag{20}$$

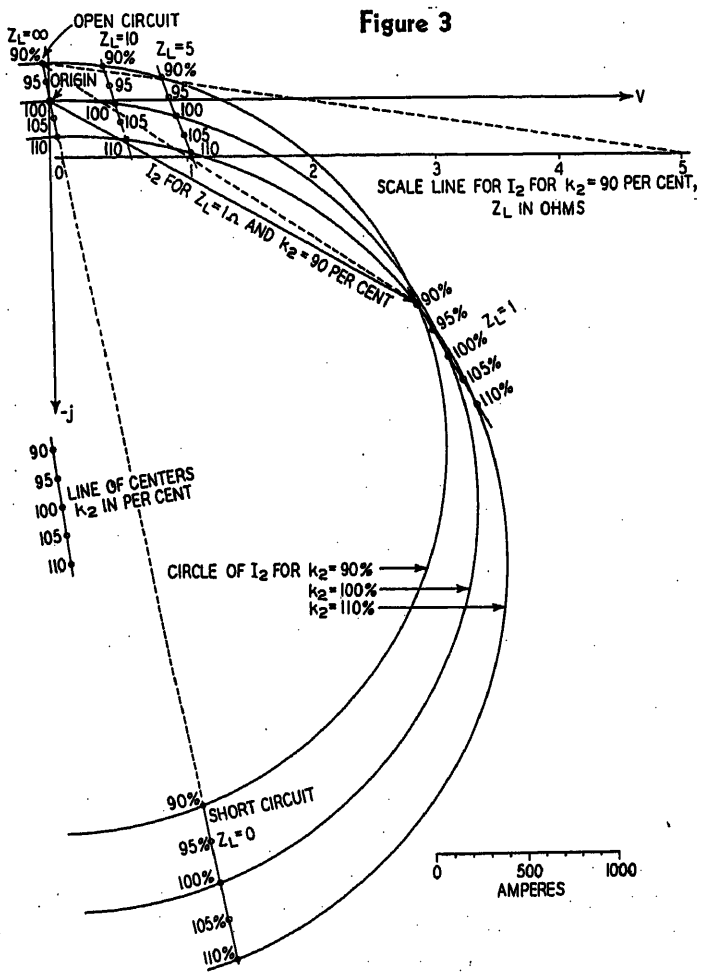
This equation is linear in both numerator and denominator with respect to all variables and therefore follows a circular locus with $Z_L$, $k_1$, or $k_2$ considered as the variable. The construction of the circular loci of $I_1/I_2$ may be carried out in the same manner as indicated for the individual loci of $I_1$ and $I_2$.

For convenience in reference the various equations and constants necessary for the cases treated above have been grouped together in chart form and tabulated in table I.

With the analysis that has just been presented, the engineer has at his disposal a complete set of equations which permits ready plotting of the currents or current ratios for parallel transformer operation, as a function of any of the variables encountered in practice.

## Numerical Example

To illustrate the application of this method to a typical problem, the circular loci of $I_1$ and $I_2$ will be determined for the following 2 transformers:



| | Transformer 1 | Transformer 2 |
|---|---|---|
| High-tension terminal voltage | 33,000 volts | 33,000 volts |
| Low-tension terminal voltage at open circuit | 6,600 volts | 6,600 volts |
| Rating | 3,000 kva | 1,500 kva<br>3,000 kva |
| Rated low-side current | 455 amperes | 227.5 amperes |
| Percentage leakage reactance | 12 per cent | 5 per cent |
| Percentage resistance | 2 per cent | 1 per cent |
| Percentage impedance | 12.2 per cent | 5.1 per cent |
| Equivalent impedance reduced to low side | $0.2915 + j1.745$ ohms<br>$1.77\angle 80.5°$ ohms | $0.289 + j1.45$ ohms<br>$1.48\angle 78.7°$ ohms |
| Transformer ratio $k$ | 0.2 | 0.2 |

The load will be taken at unity power factor. Then $Z_L = 1\angle 0° \, |Z_L|$

$Z_1 Z_2 = -2.44 + j0.926 = 2.61 \angle 159.2°$
$Z_1 + Z_2 = 0.5805 + j3.195 = 3.24 \angle 79.7°$

The loci of the individual transformer currents will be obtained for the ratios $k_1 = k_2 = 0.2$ as given above. The ratio of 0.2 will be considered as 100 per cent. To indicate how readily a family of circles can be plotted with the assumption that the change in internal impedance may be neglected for small changes in ratio, the ratio $k_1$ will be kept constant and the ratio $k_2$ will be treated as a parameter for the family. The high-tension terminal voltage $V$ will be taken as the reference vector throughout.

Figure 3

## Locus of $I_1$

Inserting the constants into equation 4 the current $I_1$ in transformer 1 becomes

$$I_1 = 33{,}000 \frac{0.2(0.289 + j1.45) + (0.2 - k_2) \, | \, Z_L \, |}{(-2.44 + j0.926) + (0.5805 + j3.195) \, | \, Z_L |} \qquad (21)$$

Two circles will be determined, for $k_2 = 0.18$ and 0.20, that is for ratios of 90 and 100 per cent, respectively, for transformer 2. The circles will be plotted by obtaining the invariant points and one other point on each, which in this case will be taken at $Z_L = 1$ ohm. The 2 sets of points for the circles are as shown in table II.

The 2 circles as determined by these points are drawn in figure 2. Straight lines are drawn connecting points of equal load impedance on the 2 circles. The intervals on these lines are used as scales for locating corresponding points on circles for $k_2$ = 95, 105, and 110 per cent. A straight line is drawn through the center points and the interval on this line is employed as a scale for obtaining the centers of the other circles. A scale line is drawn for the

Table II

| | $I_1$ Amperes | |
|---|---|---|
| $Z_L$ | $k_2$ = 90 Per Cent | $k_2$ = 100 Per Cent |
| 0 | $3{,}730 \angle -80.5°$ | $3{,}730 \angle -80.5°$ |
| 1 | $2{,}195 \angle -39.4°$ | $2{,}160 \angle -35.6°$ |
| ∞ | $203.5 \angle -79.7°$ | 0 |

90-per-cent circle. The value of $I_1$, in magnitude and phase, for any value of $Z_L$, is obtained by placing a straight edge on the infinity point and the desired value of $Z_L$ on the scale line. The intersection of the straight edge with the circle is then the extremity of the vector $I_1$ for the particular value of $Z_L$. A similar scale line may be drawn for another circle and points of $I_1$ for various values of $Z_L$ spotted on it. Straight lines connecting corresponding points on these circles suffice to locate corresponding points of $I_1$ on the other circles. Such lines are shown for $Z_L$ = 5 and 10 ohms. A scale line was drawn for the 110-per-cent circle for this purpose, but it is omitted in the figure for the sake of clarity.

To verify the construction the center vectors and the radii of the 2 circles may be calculated. From equations 15 the constant $Q$ is

$$Q = 2[-3.195 \times 2.44 - 0.926 \times 0.5805] = -16.7 \qquad (22)$$

The center vectors are then computed from equation 14 which gives

$$C_1 = j \frac{33{,}000}{-16.7} \Big[ 0.2(0.289 + j1.45)(0.5805 - j3.195) - (0.2 - k_2)(-2.44 - j0.926) \Big] \qquad (23)$$

when $k_2 = 0.18$ (90 per cent), $C_1 = 1{,}990 \angle -89.9°$
when $k_2 = 0.20$ (100 per cent), $C_1 = 1{,}890 \angle -91.0°$

From equation 18 the expression for the radius becomes

$$R_1 = \left| \frac{33{,}000 \times 1.48}{16.7} \Big[ (0.2915 + j1.745)(0.2 - k_2) - 0.2(0.5805 + j3.195) \Big] \right| \qquad (24)$$

when $k_2 = 0.18$ (90 per cent), $R_1 = 1{,}795$
when $k_2 = 0.20$ (100 per cent), $R_1 = 1{,}890$

## Locus of $I_2$

Under the same conditions, using equation 8 the current $I_2$ in transformer 2 becomes

$$I_2 = 33{,}000 \frac{k_2(0.2915 + j1.745) - (0.2 - k_2) \, | \, Z_L \, |}{(-2.44 + j0.926) + (0.5805 + j3.195) \, | \, Z_L |} \qquad (25)$$

The same 3 points on the 2 circles for different ratios $k_2$ are as shown in table III.

These circles are plotted in figure 3. Connecting lines are drawn through equal values of $Z_L$ to obtain corresponding points on circles for other values of $k_2$. A scale line is shown for the 90-per-cent circle. Points are indicated

**Table III**

| | $I_2$ (Amperes) | |
|---|---|---|
| $Z_L$ | $k_2$ = 90 Per Cent | $k_2$ = 100 Per Cent |
| 0 | 4,025 ∠ −78.7° | 4,470 ∠ −78.7° |
| 1 | 2,310 ∠ −30.2° | 2,590 ∠ −33.8° |
| ∞ | 203.5 ∠ 100.3° | 0 |

on the circles of $I_2$ for $k_2$ = 95, 105, and 110 per cent, but only the 110-per-cent circle is drawn in.

The center vectors in this case from equation 16 are:

$$C_2 = j\,\frac{33{,}000}{-16.7}\Big[k_2(0.2915 + j1.745)(0.5805 - j3.195) + (0.2 - k_2)(-2.44 - j3.195)\Big] \quad (26)$$

when $k_2$ = 0.18 (90 per cent), $C_2$ = 1,960 ∠ −90.2°
when $k_2$ = 0.20 (100 per cent), $C_2$ = 2,270 ∠ −89.2°

The radii are obtained from equation 19 which gives

$$R_2 = \left|\frac{33{,}000 \times 1.77}{-16.7}\Big[(0.289 + j1.45)(0.2 - k_2) + k_2(0.5805 + j3.195)\Big]\right| \quad (27)$$

when $k_2$ = 0.18 (90 per cent), $R_2$ = 2,150
when $k_2$ = 0.20 (100 per cent), $R_2$ = 2,270

# Mechanical Engineering in the Electrical Industry

PROBABLY no other industry in the world offers the variety and scope for mechanical engineering that the electrical business does, according to the article "The Young Mechanical Engineer in the Electrical Industry," by A. R. Stevenson, Jr. (A'20) and E. E. Parker, which was published in *Mechanical Engineering* for October 1937, pages 725–31.

Electrical engineering is so interwoven with mechanical engineering that the electrical engineer must be familiar with mechanical matters, and, vice versa, the mechanical engineer should know considerable about electrical matters. Even in nonelectrical industries, the design of machinery includes application of electric motors and control. Because electrical engineering is recognized as a separate branch, the fact is sometimes overlooked that the design and manufacture of electrical apparatus involve to a large degree work designated as mechanical engineering. For example, after an electrical engineer has decided on the size and type of punchings and windings to give the proper magnetic-flux distribution and the insulation and electrostatic shields to give the proper distribution of electric potential, someone must do the mechanical engineering involved in designing the supporting structure, determining the heat transfer, the fluid flow of the cooling media, the lubrication, and similar factors. Furthermore, factory processes for construction of the apparatus are also purely mechanical.

Electrical apparatus is seldom used alone. It is either driven by mechanical apparatus or it drives or controls some other machinery. The electrical manufacturer, therefore, must have application engineering departments to study and sales departments to keep in touch with the mechanical industries, so that he can make proper recommendations with regard to the application of electric equipment in those industries.

The variety of mechanical engineering engaged in by an electrical company extends from the design and manufacture of kitchen mixers, clothes washers, dishwashers, and other household appliances to the design and construction of locomotives and large steam turbines. Switchgear and industrial-control apparatus, although nominally classed as electrical apparatus, depend for their success largely upon the mechanical design of the parts. For instance, in the mechanism for a 287-kv circuit breaker for Boulder Dam service, compressed springs release a force of 24,000 pounds in 0.01 second when the circuit breaker is tripped, and the mechanism develops approximately 300 horsepower for 0.06 second during interruption of a circuit. These springs are compressed by a motor and are released by an electrical impulse; otherwise, the circuit-breaker mechanism is completely a mechanical-engineering job.

Most electrical manufacturers also produce a variety of related equipment which is purely mechanical in nature, having been forced to do this to develop the electrical industry to its fullest capabilities. For instance, steam-driven electric generators were limited to about 5,000 horsepower in size because of the lack of a suitable prime mover to drive them until the electrical industry developed steam turbines that could be made in larger sizes. It is the electrical industry that has pioneered the development of the steam turbine from a few hundred to many thousand horsepower. Development work on the mercury-steam binary cycle has been carried on entirely by an electrical manufacturer in co-operation with several electrical utilities. This project includes development not only of turbines to operate with mercury vapor but also mercury boilers and condensers.

# Unsymmetrical Short Circuits on Water-Wheel Generators Under Capacitive Loading

By C. F. WAGNER
MEMBER AIEE

WATER-WHEEL GENERATORS without damper windings under capacitive load may have abnormally high voltages developed across their terminals at times of unsymmetrical short circuits. These voltages are due to 2 causes. First, the difference in permeance of the magnetic circuit in the direct and quadrature axes produces, under unsymmetrical short circuits, distorted voltages which have high peak values even if there is no capacitance connected to the machine. Second, the capacitance of the line and the reactance of the machine resonate or partially resonate and produce still greater distortion of the voltages on the sound phase. The phenomenon associated with single-phase short circuits with no connected capacitive load, has been analyzed by Doherty and Nickle.[1] The present paper is concerned with the effect of the capacitive load and an analysis of the factors involved in this phenomenon. Consideration is given to the system conditions under which these harmful voltages may arise and the remedial measures which may be applied for their elimination.

The practical value of this investigation arises from the damage that might occur to system insulation or the destruction of lightning arresters that might ensue if such voltages are permitted to exist. As a matter of interest, the problem was first drawn quite forcibly to our attention by the destruction of an arrester in the field, the circumstances having been such as to present incontrovertible proof that the failure was due to the presence of excessively high sustained voltages; conditions which arresters are not expected to withstand. Relay tests were being made on an unloaded transmission line connected through a transformer to a synchronous generator without damper windings. Upon the application of a line-to-line short circuit the arrester failed. In a repeat test the arresters were removed and the line-to-ground voltages were measured and found to be of such magnitude as to account for the arrester failure. It is quite probable that other arrester failures, previously attributed to lightning or other causes, can also be explained on this basis.

The body of the paper is concerned with an oscillographic study of the factors involved in the general problem and the appendix with an analytical study of the terminal voltages which appear for a terminal-to-terminal short circuit on a generator under capacitive load.

## Nature of Phenomenon

In order to form a preliminary idea of the nature of the phenomenon, a terminal-to-terminal short circuit and a capacitive load were simultaneously applied to a 100-kva 2,300-volt generator without damper windings operating at half rated voltage. Oscillograms were taken of the voltage from the shorted phases to the sound phase. As shown in the appendix from theoretical considerations, resonating points are encountered as the capacitive load is progressively decreased from a large value. If the reactance to neutral of the capacitance load at fundamental frequency is denoted by $x_c$ and the reactances of the generator to neutral in the direct and quadrature axes are denoted by $x_d'$ and $x_q$, respectively, then resonating points are reached when the quantity $x_c/\sqrt{x_d'x_q}$ is equal to $n^2$, where $n$ may be any odd integer. Oscillograms are shown in figure 1 for a wide variation of $x_c/\sqrt{x_d'x_q}$. Beginning with (*a*) it will be observed that the voltage consists of a fundamental component with a pronounced third harmonic. As $x_c/\sqrt{x_d'x_q}$ increases the fundamental decreases and the third harmonic increases, until a maximum deflection, as compared with the no-load value before the short circuit, is reached in oscillogram (*e*). This oscillogram has a value of $x_c/\sqrt{x_d'x_q}$ of 8.65 which does not correspond exactly to the theoretical value of 9. However, the computed value was based upon values of $x_d'$ and $x_q$ for normal frequency and rated current. Actually $x_d'$ and $x_q$ may not be regarded as constant. In figure 2 $x_d'$ and $x_q$ are plotted as functions of frequency for constant current and in figure 3, as a function of current for rated frequency. The root-mean-square value of the short-circuit current of figure 1*e* varies with time but is of the order of 1.2 to 1.4 per unit.* If it is assumed that the current is 1.25 per unit and that the reactances at this current vary in the same proportion as for the smaller currents in figure 2 then the corrected value of $x_c/\sqrt{x_d'x_q}$ is 9.1. This constitutes a very close check upon the theory.

As $x_c/\sqrt{x_d'x_q}$ is further increased the third harmonic becomes smaller and the fifth harmonic larger. This is progressively illustrated until oscillograms (*j*) and (*k*) are reached. Resonance occurs between these 2 oscillograms at a value somewhat smaller than the theoretical value of 25. Continuing still further, the seventh harmonic reaches a maximum in oscillogram (*o*). The voltage resulting for a terminal-to-terminal short circuit with no connected capacity is shown in (*q*). Theoretically, of course, if the resistance is negligible the voltage for the different resonating points should be infinitely large. Actu-

A paper recommended for publication by the AIEE committees on electrical machinery and power generation. Manuscript submitted June 10, 1937; released for publication September 16, 1937.

* In this paper the per-unit system is used in designating the machine constants.

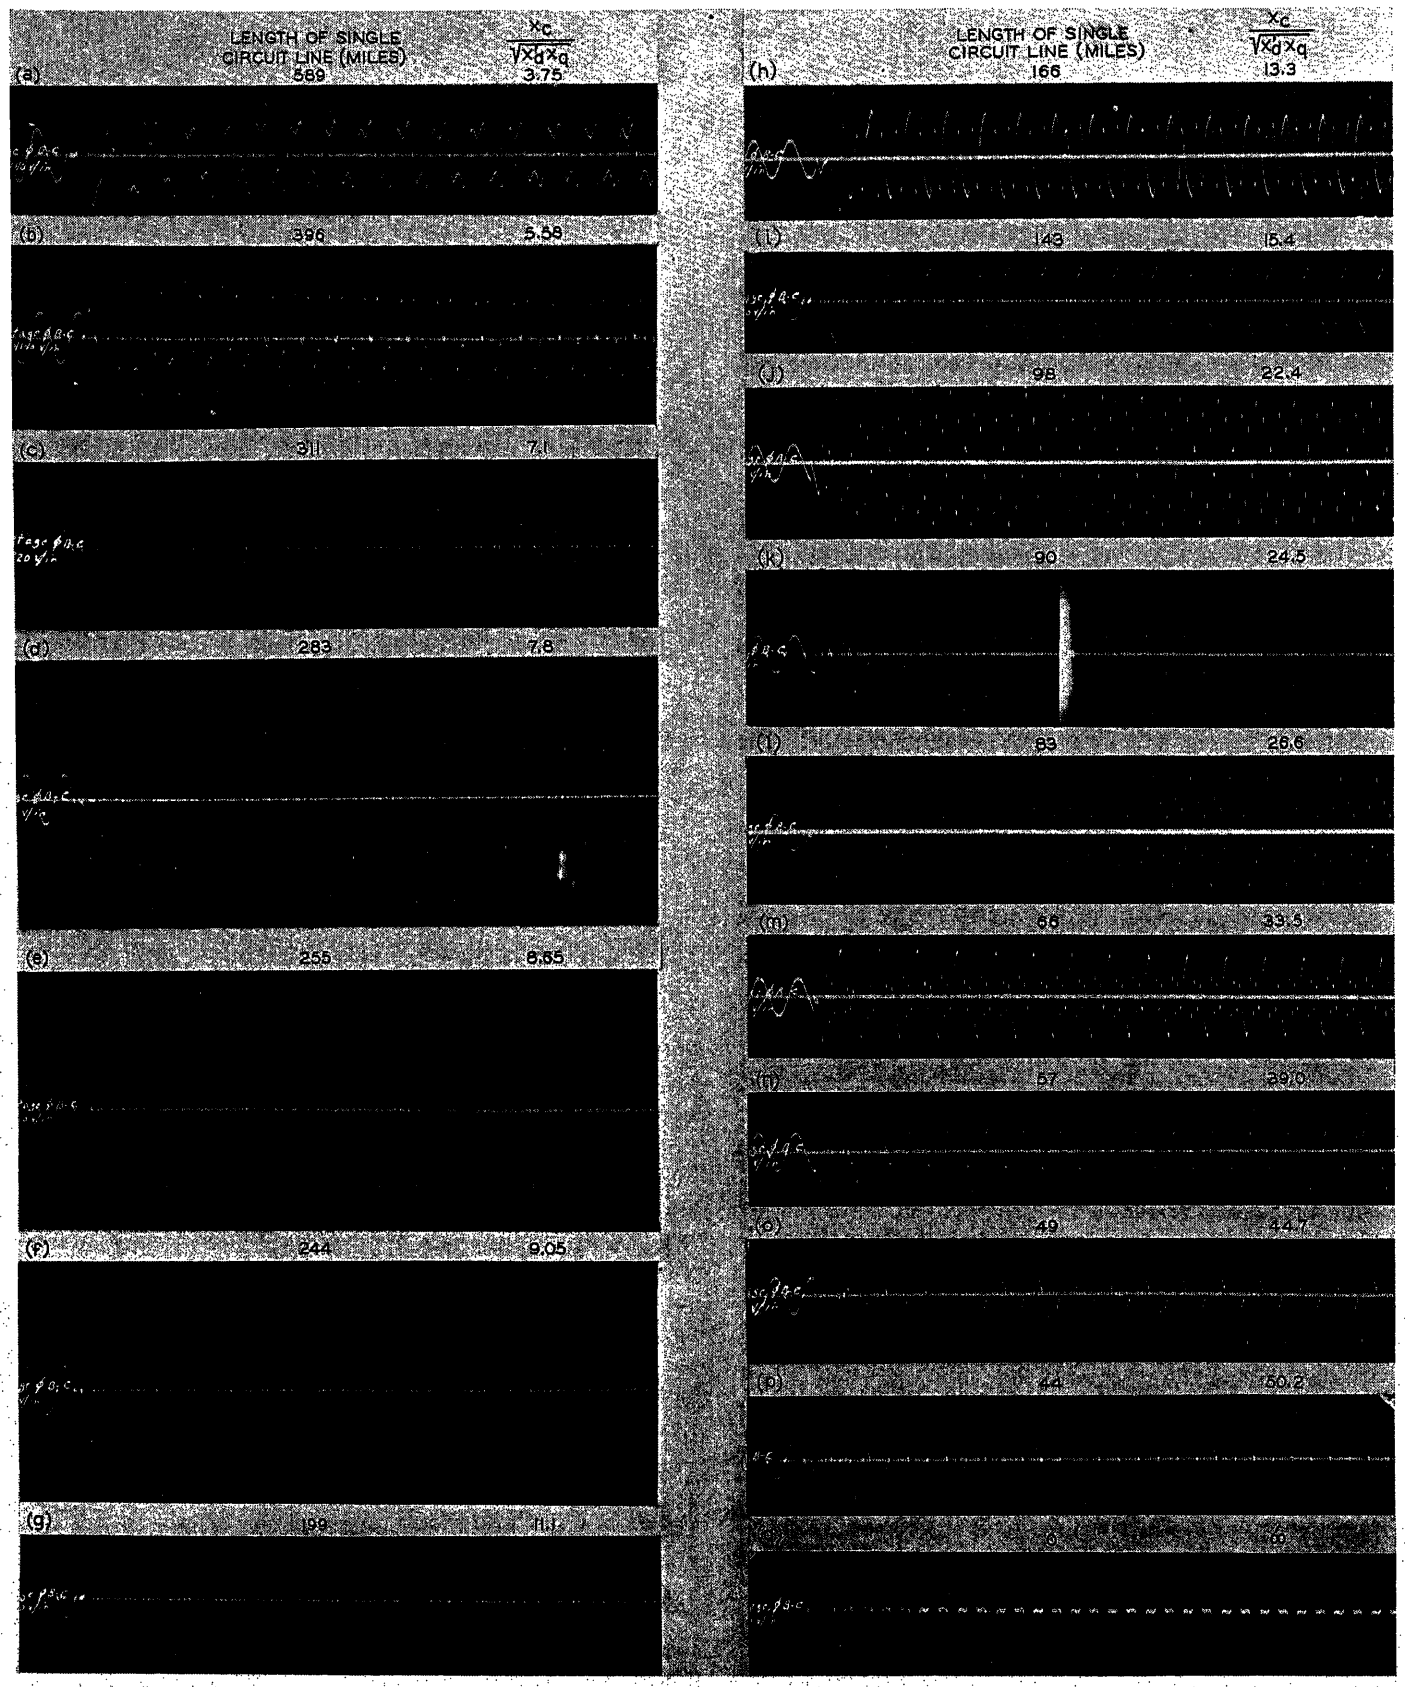

**Figure 1. Effect upon the terminal voltage of varying the shunt capacitive reactance when a terminal-to-terminal short circuit is applied to a machine without damper windings**

ally the resistance limits the magnitude to which the voltage rises, its effect increasing as the frequency increases. The truth of this statement is borne out by the curves of resistance for the 2 axes plotted in figure 2. These values were obtained by applying single-phase potential of variable frequency across 2 terminals of the machines with the rotor stationary as is done in the conventional method for determining $x_d''$ and $x_q''$. The resistance components of the impedances in the 2 axes are indicated as $r_{ad}''$ and $r_{aq}''$. It will be observed that for the seventh harmonic $r_{aq}''$ is 0.68 and $r_{ad}''$ is 0.17, values sufficiently high to significantly limit the voltages for resonance at this frequency. The curves of figure 2 were taken at the small currents indicated because of limitations

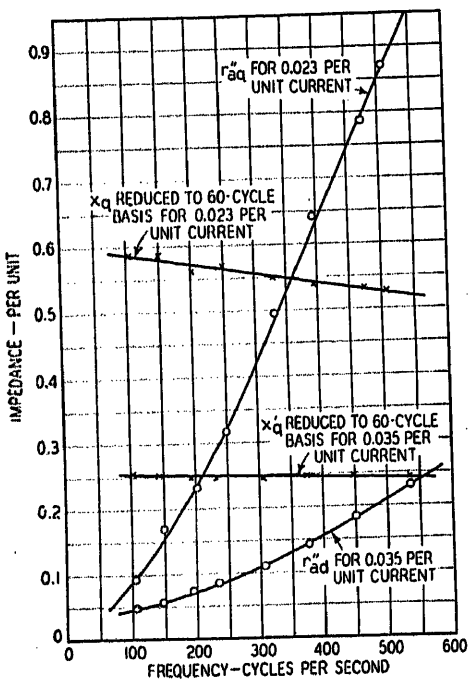

**Figure 2. Variation of $x_d'$, $x_q$, $r_{ad}''$, and $r_{aq}''$ with frequency**

100-kva 2,300-volt machine without damper winding

in the power of the source. The general effect of resistances will be discussed further in the appendix.

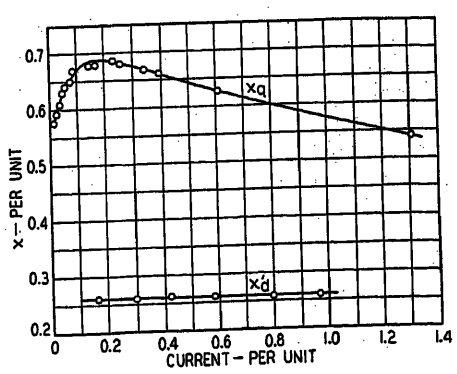
It will be observed that under certain conditions an initial transient of quite high value is present. This usually occurs at even harmonic resonant values of $x_c/\sqrt{x_d' x_q}$ as evidenced by oscillograms (*a*), (*b*), and (*h*). The point of greatest significance in connection with these oscillograms is that the maximum voltages occur for resonant conditions near the third and fifth harmonics.

In order to orient one's self with regard to the length of line involved in these considerations, the figure in miles which appears above each oscillogram represents approximately the length of single circuit 66-kv or 220-kv transmission line which, with a generator having the characteristics of the one used in the test, is required to satisfy the given value of $x_c/\sqrt{x_d' x_q}$. These figures were arrived at by assuming a generator capacity of 25,000 kva, 75,000 kva, and 200,000 kva for a 66 kv, 132 kv, and 220 kv, respectively. For smaller machines the length will decrease in proportion.

## Effect of Parallel Machines Having Damper Windings

In practice water-wheel generators are usually paralleled with machines having damper windings or their equivalent, that is, the generator may feed power over a line into a system which includes turbogenerators or, again, synchronous condensers may be connected to the system at the receiving end of the line. Under what conditions then may these harmful voltages appear and to what extent do parallel machines hold these voltages down? If upon the inception of a fault upon a single-circuit transmission line to which a generator without damper windings is connected, the breaker at the end remote from the generator opens first, then the condition prevails under which it is known these abnormal voltages can exist, namely, an essentially capacitive load connected to a machine without damper windings. This condition will persist until the breaker at the supply end is opened. During the interval while both breakers are closed, the machines with damper windings reduce the maximum voltages. If the line involved is a 2-circuit line, then opening the breaker at the receiving end of one line does not open the tie between the 2 ends of the system and the dangerous condition of having an open line tied to a generator cannot exist unless the second breaker at the receiving end is opened.

The extent to which connected machines with damper windings are effective is illustrated in figure 4. The schematic diagram shows the arrangement of the test equipment which represents a transmission system in miniature. Machine 1 is a generator *without* damper windings and machine 2 is a generator with *end-connected copper* damper windings. The intervening transmission line is representative of a 100-mile single-circuit line. Oscillogram (*b*) shows the phase-to-ground voltage for a phase-to-phase short circuit on the left-hand side of the line and oscillogram (*a*) the same voltage for the condition in which machine 2 is not connected to the line. The calibration of the oscillograph elements was not the same in these 2 cases, but by comparing the deflections with the no-load voltages before the short circuit it may be seen that the presence of the machine with copper dampers reduces the peak voltages to 68 per cent. In taking oscillogram (*a*) the series reactance ($j0.47$) was not in the circuit but its omission will not change the conclusions. The significant factor is that the harmonics are suppressed to a very great extent. Oscillograms (*c*) and (*d*) were taken under con-



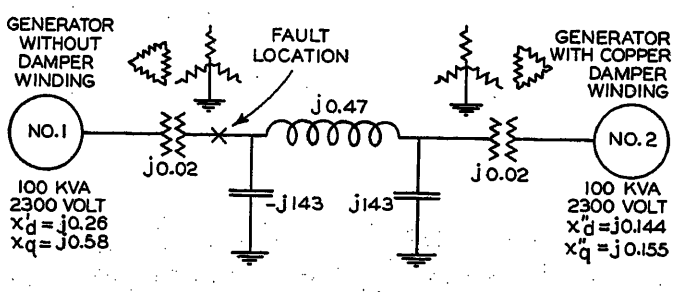


**Figure 3. Variation of $x_d'$ and $x_q$ as a function of current**

100-kva 2,300-volt machine without damper windings

ditions identical to (*a*) and (*b*), respectively, except that the fault was a line-to-neutral short circuit. For shorter transmission lines or any case in which there is less reactance between the machines, the damper windings will be still more effective in limiting the excessive voltages.

## Effect of Load

The question naturally arises as to the effect of connected load in suppressing the harmonics associated with these voltages. If load is taken from the generator end of a transmission line will a short circuit on an open-ended transmission line connected to the bus result in smaller voltages than if the load were absent? Oscillographic

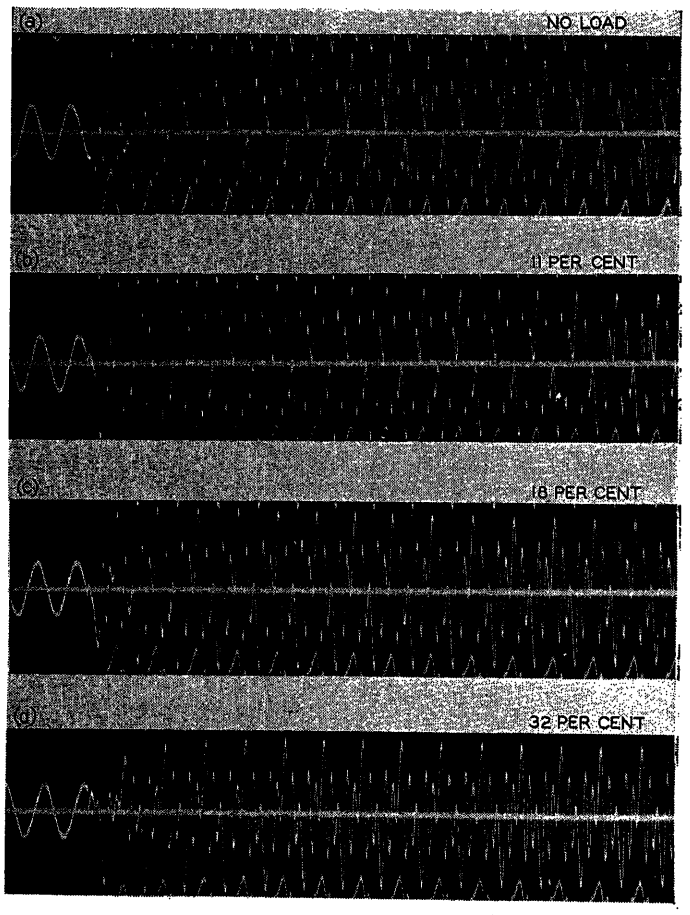

**Figure 5. Effect of pure reactance load**

tests were made on a 100-kva generator loaded with capacitors through a delta-star transformer. The capacitance was equal to 8.85 per unit and approximates the lengths of single-circuit line given in the last column of table I. It must be borne in mind that a capacitor is not strictly analogous in characteristics to a transmission line, especially at the higher frequencies, but it is sufficiently representative for the purpose in hand. Loads of different character were then applied to the line side of the transformer.

### Pure Reactance

Figure 5 shows the results of tests made with essentially pure reactance loads. To preclude the need for obtaining 3-phase reactors the load in the form of a single reactor was applied simultaneously with a phase-to-phase short circuit on the line. The capacitors were connected at the same time. The line-to-ground voltage of the unshorted phase on the load side of the transformer is shown by the oscillograms for reactor values equivalent to steady-state loads of 0, 11, 18, and 32 per cent of rated values. The reactor loading over the entire range has little if any effect upon the magnitude of these voltages or in suppressing harmonics unless very near a resonance point in which case the reactor would dissonate or detune the circuit. Thus the reactive load merely changes the resonating points. Of course, as the load reactance is still further decreased the voltage will decrease, approaching zero as the load reactance approaches zero.

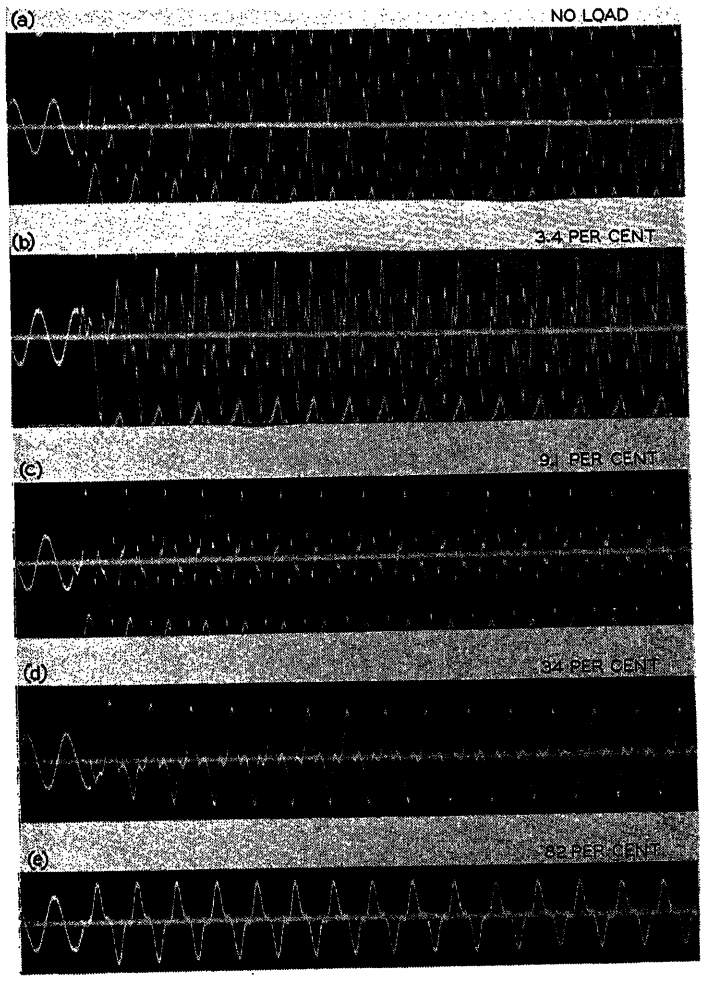

Figure 6. Effect of pure resistance load

PURE RESISTANCE

Pure resistance load, on the other hand, becomes quite effective in reducing the voltage of the sound phase as may be evidenced by the oscillograms of figure 6. A load of 34 per cent reduced the sound phase voltage to about 65 per cent of the voltage for the no-load condition.

INDUCTION MOTOR

An induction-motor load of equal kilovolt-amperes is still more effective in reducing the peak voltages than is a pure resistance load. The upper 3 curves of figure 7 show the effect upon the sound phase-to-neutral voltage on the load side of the transformer as a phase-to-phase short circuit, the capacitor load, and an induction-motor load of 0, 12.2, and 49 per cent, respectively, are simultaneously applied to the 100-kva generator. A 25-horsepower induction motor was used for this purpose, the generator being operated at half voltage and the induction motor at such voltages, by means of transformers, as to produce an impedance equivalent to the loads indicated. The induction motors were unloaded. By comparing the oscillogram voltages with the values before the short circuit, it will be seen that induction motors are quite effective in reducing these abnormal voltages. This is due to the lower impedance for the harmonics than that possessed by a proportionate pure reactance load.

The lower 3 oscillograms give verifying results for phase-to-neutral short circuits.

## Damper Windings

It is shown in the appendix that for a terminal-to-terminal short circuit on an unloaded machine *without* damper windings the voltage from the sound phase to the shorted phases can be resolved into odd and even harmonics. The even harmonics, including the zero'th, decay quite rapidly (within a few cycles if several per cent resistance, representative of that in a transmission line, is inserted in the armature circuit) and the odd harmonics more slowly. The crest value of the sum of the odd harmonics just after short circuit is equal to $(3/2)/(x_q/x_d')$ times the crest of the normal line-to-neutral voltage. For a machine *with* damper windings this multiplying factor is $(3/2)(x''/x_d'')$. Thus the crest voltages, neglecting the rapidly decaying even harmonics, increase proportionately

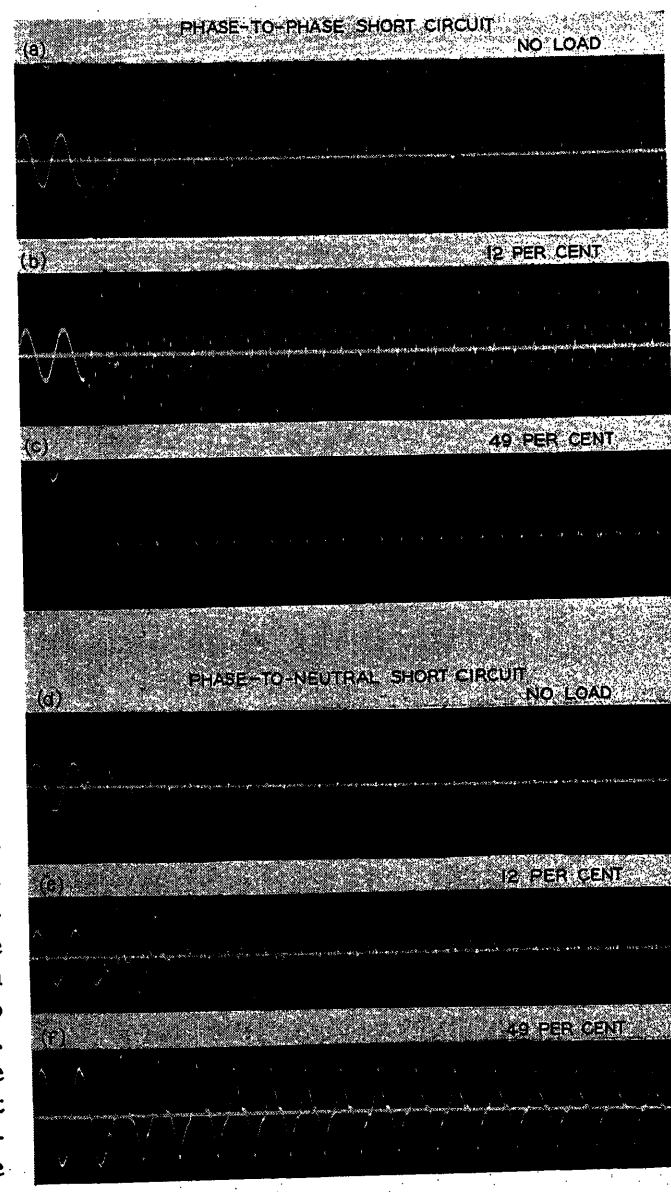

Figure 7. Effect of induction-motor load

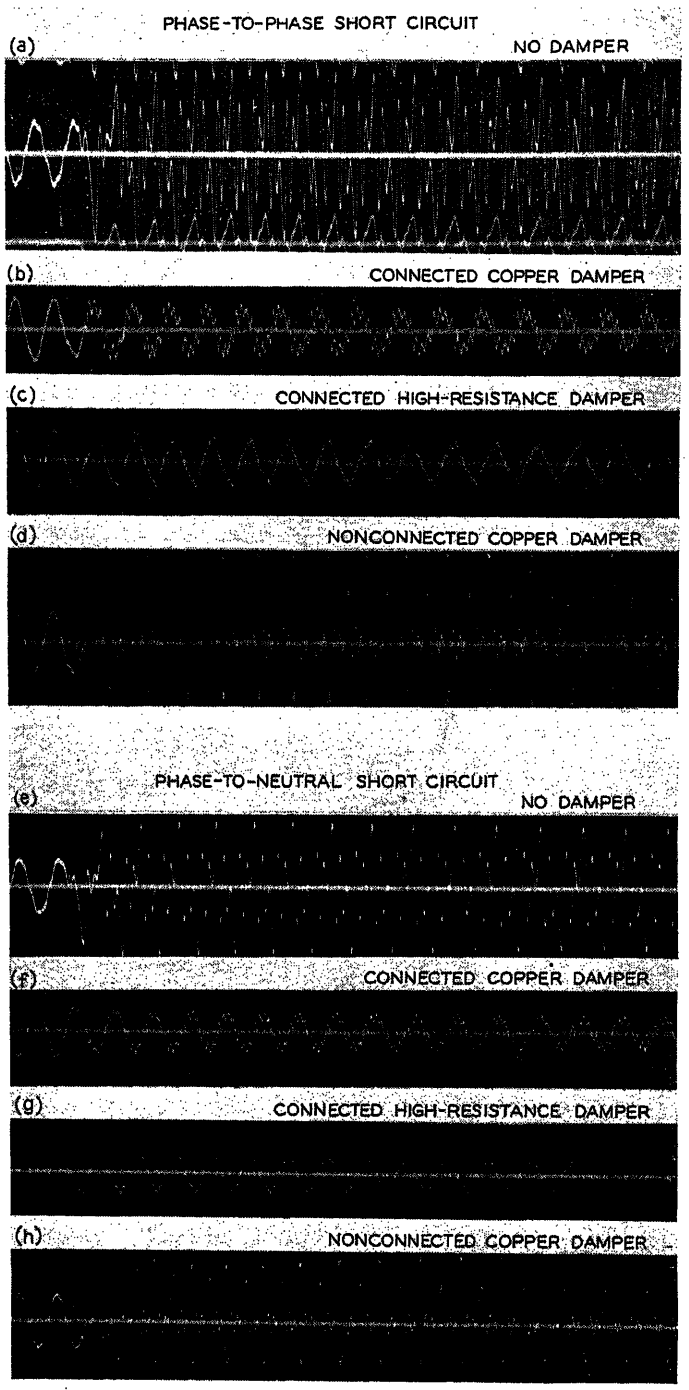

**Figure 8. Effect of damper windings**

:o the ratio $x_q/x_d'$ for machines without damper windings and to the ratio $x_q''/x_d''$ for machines with damper windings. One would expect also that the abnormal voltages encountered under capacitive loading might also vary with $x_q/x_d'$ or $x_q''/x_d''$.

Tests were made on 3 100-kva synchronous generators that were identical except as to damper windings. One of the machines had no damper windings, one a copper damper, and the other an Everdur* or high-resistance damper. In addition, the tests were repeated with the machine with copper dampers after the end straps had been insulated between poles thus constituting in effect a nonconnected damper winding. The constants of the machines are given in table II. Each of the machines was in turn connected through a delta-wye bank of 3 $37\frac{1}{2}$-kva transformers to a capacitive load consisting of capacitors connected from the phase wires to the neutral point of the transformer secondary. The capacitors were of such magnitude to simulate the line lengths represented in table I.

The specific tests consisted of phase-to-phase and phase-to-neutral short circuits, the results of which are shown by the oscillograph study of figure 8. It will be observed that for both kinds of short circuits, the voltages are reduced considerably by the presence of connected dampers, whether they be of the low-resistance (copper) type or the high-resistance (Everdur) type. To this extent the surmise is borne out that the ratio $x_q''/x_d''$ constitutes a rough measure of the distortion one might expect. In oscillograms (*a*) and (*e*), the combination of machine reactance and line capacitance is such as to be near the resonance point for the fifth harmonic but with the decrease in machine reactance occasioned by the copper damper (the line capacitance remaining the same) the resonance point has been moved closer to the seventh as shown in oscillograms (*b*) and (*f*). For the machine with Everdur dampers [oscillograms (*c*) and (*g*)], the reactance is such as to also approach the resonating point for the seventh harmonic, but it will be observed that the amplitude of the harmonic is much smaller than that for the copper damper winding. This is because the higher values of $r_{ad}''$ and $r_{aq}''$ for Everdur (see table II) tend to prevent to a greater extent the building up of the large currents and voltages associated with resonant conditions.

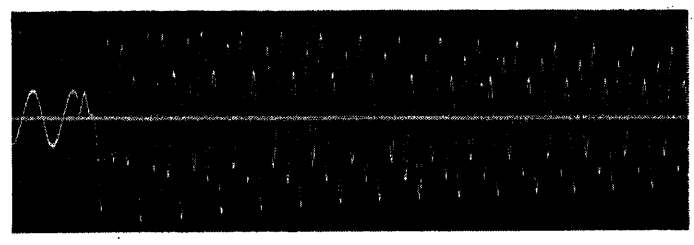

**Figure 9. Terminal-to-terminal voltage across sound phase for simultaneous application of terminal-to-terminal short circuit and capacitor load for a machine with nonconnected copper damper windings**

Circuit near third harmonic resonance

While in this case, nonconnected dampers are not anywhere near as effective as connected dampers in reducing the peak voltages, they are somewhat more effective than no dampers. Additional terminal-to-terminal short circuits were made on machines with nonconnected damper windings under capacitive load covering a wide range of capacitance. The case for near resonance of the third harmonic is shown in figure 9. By comparison with figure 1*e* it may be seen that the voltages from the sound phase to the short-circuited phases are somewhat less. This is

* The conductivity of Everdur is approximately 6 per cent.

probably due to larger values of $r_{ad}''$ and $r_{aq}''$ for the machine with nonconnected dampers. Table II shows a variation of these constants in this general direction and at 180 cycles the difference is probably greater. In any case figures 8*d* and 8*h* show that dangerously high voltages can be attained with this kind of damper unless precautions are taken to insure that the ratio $x_q''/x_d''$ is made more nearly equal to unity.

Additional data[4] relative to the effect of damper windings upon the constants of machines are given in table III.

## Conclusions

It has been shown that dangerously high voltages can be attained under unbalanced short circuits when synchronous generators without damper windings are connected to capacitive loads such as represented by an unloaded transmission line. These voltages may consist of very high initial transients of a few cycles duration followed by

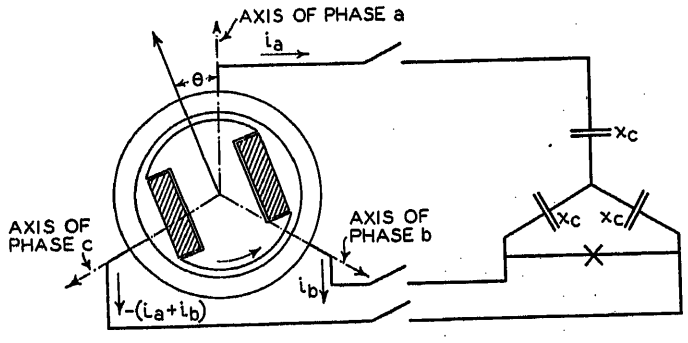

Figure 10

distorted waves having a slower decay. For a given machine resonating points are encountered as the length of unloaded connected line is varied. The voltages are maximum at these resonating points. The length of line required for resonance is also dependent upon the type of fault considered. A particular line represents a particular electrostatic capacity but since the fault may occur at any point, the reactance is variable. This fact increases the difficulties of attempting to operate at a point of dissonance. In general if conditions are such that resonance is obtained for a short circuit at the generator end of the line, the voltages that can be expected will be larger than if conditions are such as to produce resonance for short circuits at the far end of the line. This follows because the resistance of the line tends to prevent the building up of the currents and voltages at resonance. These abnormal voltages are larger in proportion to normal values on the line side of transformers than on the machine side.

If other synchronous machines having damper windings or their equivalent are kept in parallel or if sufficient resistance or induction-motor load is maintained connected to the machines, the excess voltages may be reduced a very considerable degree.

It has been shown that these phenomena are very closely associated with the ratio $x_q/x_d'$ in the case of machines without damper windings and $x_q''/x_d''$ in the case of machines with damper windings, the magnitude of the abnormal voltages increasing as this ratio increases from unity. Connected damper windings, either high or low resistance, because their presence results in a machine for which this ratio is very nearly equal to unity, are very effective in preventing these abnormally high voltages. Damper windings which result in a higher value of this ratio, such as may be the case for windings not connected between poles, are not so effective in preventing these voltages.

Tests have shown (figure 1*e*) that the crest value of the voltage from the sound phase to the shorted phases may attain a value 5.5 times the normal crest line-to-line value. Without making an attempt to obtain resonant conditions, the line-to-neutral voltages for a line-to-line short circuit (figure 8*a* and 8*d*) gave a measured value of 2.9 times normal crest value for both a machine with connected and one with nonconnected copper damper windings.

## Appendix

In approaching the analytical investigation of this problem the simplest case will be chosen which still incorporates the essential

**Table I. Lengths of Single-Circuit Transmission Lines Having Capacitance Impedance of 8.85 Per Unit**

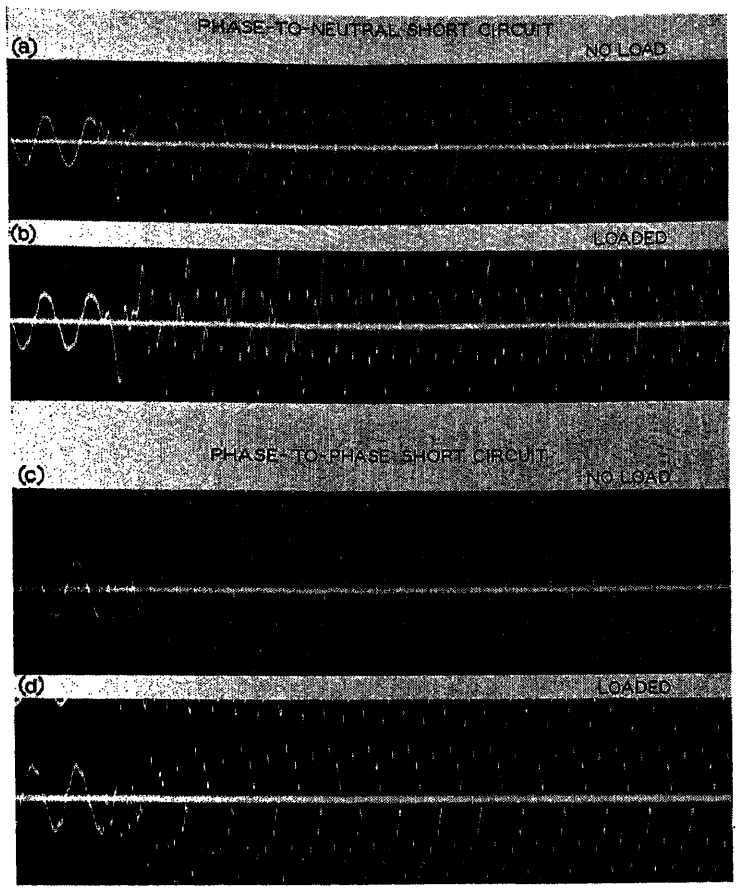

**Figure 11. Effect of loading machine with capacitive load before short circuit**

factors of the problem. To this end consideration will be given to the voltage between the short-circuited and the sound terminals of a synchronous machine without damper windings as a terminal-to-terminal short circuit and a 3-phase capacitive load are applied simultaneously. The schematic diagram of the circuit is shown in figure 10. The notation and assumptions will be the same as that used by Park[2,3] in his papers relating to the theory of synchronous machines. Thus the machine will be "idealized" to the extent that each armature winding will be assumed to produce a sinusoidal wave of magnetomotive force. Saturation, hysteresis, and eddy currents will be neglected.

The "per unit" system will be employed in which the units are defined as follows:

| | |
|---|---|
| Armature current | $\sqrt{2}$ rated value |
| Armature voltage | $\sqrt{2}$ rated terminal-to-neutral value |
| Armature flux | value which will generate rated voltage at no load |
| Field current | value which will produce unit armature flux at no load |
| Reactance | ratio of normal phase-to-neutral voltage to normal phase current |
| Angle | electrical radian |
| Time | time for rotor moving at rated speed to move through one electrical radian |

Let

$i_a, i_b, i_c$ = terminal currents
$e_a, e_b, e_c$ = terminal-to-neutral voltages
$\psi_a, \psi_b, \psi_c$ = terminal-to-neutral linkages
$I_d$ = field current
$\theta$ = angular displacement of rotor from axis of phase $a$

From figure 10, it is evident that

$$I_c = -(i_a + i_b) \tag{1}$$

so that equation 3 of reference 3 becomes

$$i_d = \frac{2}{3}\left\{\left[\cos\theta - \cos\left(\theta + \frac{2\pi}{3}\right)\right] i_a + \left[\cos\left(\theta - \frac{2\pi}{3}\right) - \cos\left(\theta + \frac{2\pi}{3}\right)\right] i_b\right\} \tag{2}$$

The flux linkages with the field winding, $\Psi$, are given by

$$\Psi = I_d - (x_d - x_d')i_d \tag{3}$$

Therefore, corresponding to any sudden change in armature currents,

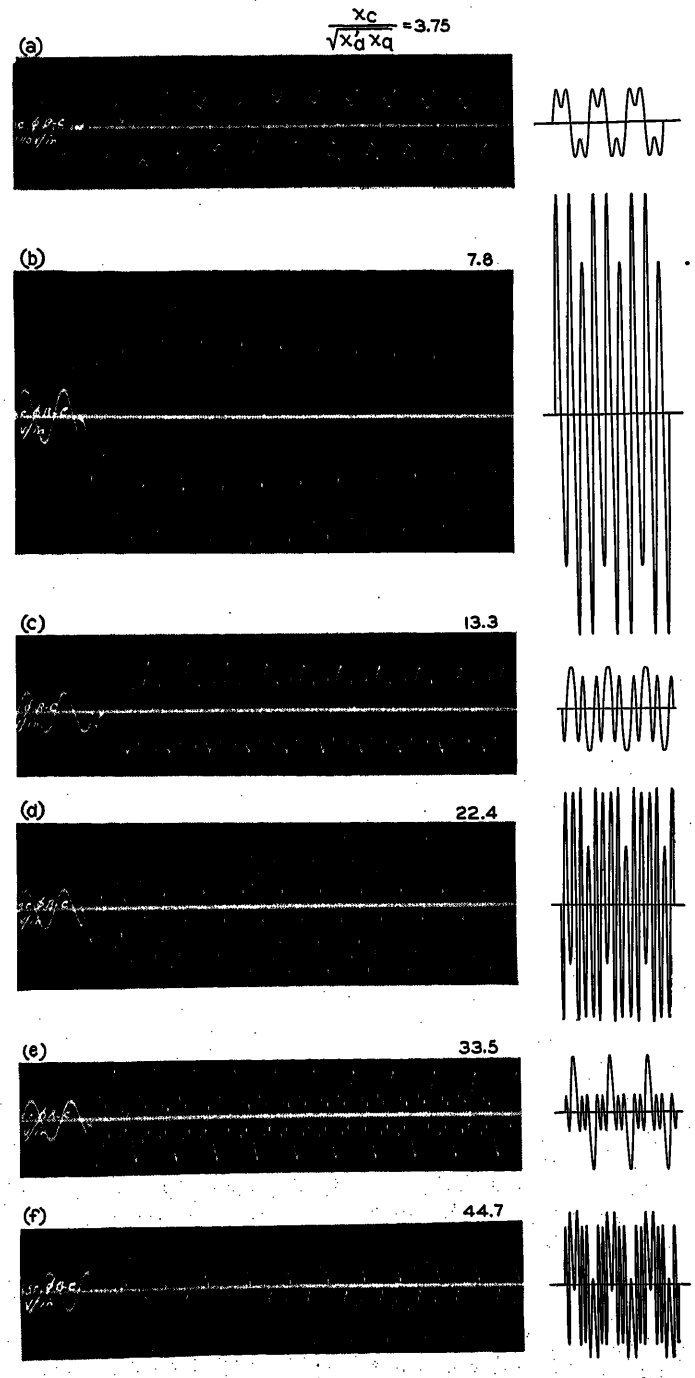

**Figure 12. Comparison between test and calculated values of voltage**

there follows from this equation (since $\Psi$ cannot change instantly) that

$$0 = \Delta I_d - (x_d - x_d')i_d \tag{4}$$

where $\Delta I_d$ is the current induced in the field winding. Therefore, upon substituting 2 in 4

$$\Delta I_d = \frac{2(x_d - x_d')}{3}\left\{\left[\cos\theta - \cos\left(\theta + \frac{2\pi}{3}\right)\right]i_a + \left[\cos\left(\theta - \frac{2\pi}{3}\right) - \cos\left(\theta + \frac{2\pi}{3}\right)\right]\right\} \tag{5}$$

Equations 1 to 3 of Park's paper give the flux linkages $\psi_a$, $\psi_b$, and $\psi_c$ for any values of $i_a$, $i_b$, $i_c$, and $I_d$. If the value of $i_c$ from 1 and $\Delta I_d$ from 5 are substituted in these equations, the values of flux linkages for the suddenly appearing armature currents are obtained. These are:

$$\psi_a = -\frac{x_d' - x_q}{3}\left\{\left[\cos 2\theta - \cos\left(2\theta + \frac{2\pi}{3}\right)\right]i_a + \left[\cos\left(2\theta - \frac{2\pi}{3}\right) - \cos\left(2\theta + \frac{2\pi}{3}\right)\right]i_b\right\} - \frac{x_d' + x_q}{2}i_a \tag{6}$$

$$\psi_b = -\frac{x_d' - x_q}{3}\left\{\left[\cos\left(2\theta - \frac{2\pi}{3}\right) - \cos 2\theta\right]i_a + \left[\cos\left(2\theta + \frac{2\pi}{3}\right) - \cos 2\theta\right]i_b\right\} - \frac{x_d' + x_q}{2}i_b \tag{7}$$

$$\psi_c = -\frac{x_d' - x_q}{3}\left\{\left[\cos\left(2\theta + \frac{2\pi}{3}\right) - \cos\left(2\theta - \frac{2\pi}{3}\right)\right]i_a + \left[\cos 2\theta - \cos\left(2\theta - \frac{2\pi}{3}\right)\right]i_b\right\} + \frac{x_d' + x_q}{2}(i_a + i_b) \tag{8}$$

In addition to the flux linkages due to the suddenly appearing armature currents there also exist flux linkages due to the normal value of field current. These values are

$$\psi_a = I_d \cos\theta \tag{9}$$

$$\psi_b = I_d \cos\left(\theta - \frac{2\pi}{3}\right) \tag{10}$$

$$\psi_c = I_d \cos\left(\theta + \frac{2\pi}{3}\right) \tag{11}$$

The total flux linkages between $b$ and $c$ for the sudden change in armature current (including the normal field current) are

$$\psi_b - \psi_c = \sqrt{3}\,I_d \sin\theta - (x_d' - x_q) \times \left[i_a \cos\left(2\theta - \frac{2\pi}{3}\right) - i_b \cos 2\theta\right] - \frac{x_d' + x_q}{2}(i_a + 2i_b) \tag{12}$$

and for the flux linkages across $a$ and $b$

$$\psi_a - \psi_b = \sqrt{3}\,I_d \sin\left(\theta + \frac{2\pi}{3}\right) - (x_d' - x_q) \times \left[i_a \cos 2\theta - i_b \cos\left(2\theta + \frac{2\pi}{3}\right)\right] - \frac{x_d' + x_q}{2}(i_a - i_b) \tag{13}$$

The voltage across the terminals $b$ and $c$ is equal to

$$\frac{d}{dt}(\psi_b - \psi_c) = 0$$

or

$$\psi_b - \psi_c = \text{constant} \tag{14}$$

The significance of this equation is that the flux linkages immediately before and immediately after short circuit are equal, an application of Doherty's theorem of "constant flux linkages." Stated otherwise, the constant is determined from the value just before short circuit. If

$$\theta = t + \alpha \tag{15}$$

in which $t$ is measured from the instant of short circuit, then

$$\sqrt{3}\,I_d \sin\alpha = \sqrt{3}\,I_d \sin\theta - (x_d' - x_q)\left[i_a \cos\left(2\theta - \frac{2\pi}{3}\right) - i_b \cos 2\theta\right] - \frac{x_d' + x_q}{2}(i_a + 2\,i_b) \tag{16}$$

or

$$i_b = \frac{\sqrt{3}\,I_d\,[\sin\alpha - \sin\theta] + \left[(x_d' - x_q)\cos\left(2\theta - \frac{2\pi}{3}\right) + \frac{x_d' + x_q}{2}\right]i_a}{(x_d' - x_q)\cos 2\theta - (x_d' + x_q)} \tag{17}$$

The voltage across terminals $a$ and $b$ is equal to the voltage across the capacitors and also the time differential of the flux linkages across $a$ and $b$ so that

$$e_a - e_b = \frac{d}{dt}(\psi_a - \psi_b) = \frac{3}{2}x_c\int_0^t i_a dt$$

Upon substituting 13 and 17 into this equation,

$$\frac{d}{dt}\left\{\sqrt{3}\,I_d \sin\left(\theta + \frac{2\pi}{3}\right) - \left[(x_d' - x_q)\cos 2\theta + \frac{x_d' + x_q}{2}\right]i_a + \frac{(x_d' - x_q)\cos\left(2\theta + \frac{2\pi}{3}\right) + \frac{x_d' + x_q}{2}}{(x_d' - x_q)\cos 2\theta - (x_d' + x_q)}\sqrt{3}\,I_d\,[\sin\alpha - \sin\theta] + \frac{(x_d' - x_q)\cos\left(2\theta + \frac{2\pi}{3}\right) + \frac{x_d' + x_q}{2}}{(x_d' - x_q)\cos 2\theta - (x_d' + x_q)} \times \left[(x_d' - x_q)\cos\left(2\theta - \frac{2\pi}{3}\right) + \frac{x_d' + x_q}{2}\right]i_a\right\} = \frac{3}{2}x_c\int_0^t i_a dt$$

or rearranging

$$\sqrt{3}\,I_d \frac{d}{dt} \times \left\{\frac{\cos\left(2\theta + \frac{2\pi}{3}\right) - \frac{x_q + x_d'}{2(x_q - x_d')}}{\cos 2\theta - \frac{x_q + x_d'}{2(x_q - x_d')}}\,[\sin\alpha - \sin\theta] + \sin\left(\theta + \frac{2\pi}{3}\right)\right\} = + (x_q - x_d')\frac{d}{dt}\left[\left\{-\left[\cos 2\theta - \frac{x_q + x_d'}{2(x_q - x_d')}\right] + \frac{\cos\left(2\theta + \frac{2\pi}{3}\right) - \frac{x_q + x_d'}{2(x_q - x_d')}}{\cos 2\theta + \frac{x_q + x_d'}{x_q - x_d'}} \times \left[\cos\left(2\theta - \frac{2\pi}{3}\right) - \frac{x_q + x_d'}{2(x_q - x_d')}\right]\right\}i_a\right] + \frac{3}{2}x_c\int_0^t i_a dt \tag{18}$$

By further manipulation, whose proof space will not permit, it may be shown that this equation can be written in the following form

$$\frac{3}{2}I_a\frac{d}{dt}f(t) = \frac{3}{2}\sqrt{x_q x_d'}\,\frac{d}{dt}[F(t)\,i_a] + \frac{3}{2}x_c\int_0^t i_a dt \tag{19}$$

in which

$$f(t) = K' [\epsilon^{j\theta} + b\epsilon^{j3\theta} + b^2\epsilon^{j5\theta} + \dots + \epsilon^{-j\theta} + b\epsilon^{-j3\theta} + b^2\epsilon^{-j5\theta} + \dots] - \sin\alpha \left[\frac{1}{\sqrt{3}} + jb\epsilon^{j2\theta} + jb^2\epsilon^{j4\theta} + jb^3\epsilon^{j6\theta} + \dots - jb\epsilon^{-j2\theta} - jb^2\epsilon^{-j4\theta} - jb^3\epsilon^{-j6\theta} + \dots\right] \quad (20)$$

$$F(t) = [1 + b\epsilon^{j2\theta} + b^2\epsilon^{j4\theta} + b^3\epsilon^{j6\theta} + \dots + b\epsilon^{-j2\theta} + b^2\epsilon^{-j4\theta} + b^3\epsilon^{-j6\theta} + \dots] \quad (21)$$

and

$$b = -\frac{\sqrt{x_q} - \sqrt{x_d'}}{\sqrt{x_q} + \sqrt{x_d'}} \quad (22)$$

$$K' = \frac{\sqrt{x_q}}{\sqrt{x_q} + \sqrt{x_d'}} \quad (23)$$

The solution sought, namely, the voltage from terminal $a$ to $b$, is equal to last term of equation 19. The terms in 19 were arranged in that particular order because it suggests an equivalent problem to which it may be reduced, namely a constant capacitor $(3/2)x_c$ and a variable reactor having a mean value $(3/2)\sqrt{x_d'x_q}$ connected in series. The reactor varies harmonically in accordance with equation 21. The problem then consists of determining the voltage drop across this constant capacitor as the voltage given by

$$\frac{3}{2} I_a \frac{d}{dt} f(t)$$

is suddenly applied across the combination. This equivalent circuit suggests that resonance points exist for values of $x_c/\sqrt{x_q x_d'}$ equal to the square of the integers. The applied voltage equals the voltage across the sound phase for a terminal-to-terminal short circuit with no connected capacitors.

The formulation of the problem which resulted in equation 19, neglected the resistances in all circuits. The effect of resistance is dependent upon the particular component of the solution affected: Thus the odd harmonics of the applied voltage decrease gradually to their sustained value along an exponential curve whose time constant, which as shown by Doherty and Nickle,[1] is

$$T_d' = \frac{1}{\sigma_f} = \frac{x_d' + \sqrt{x_d'x_q}}{x_d + \sqrt{x_d'x_q}} T_{d_0} \quad (24)$$

The even harmonics of the applied voltage decrease to zero, and their time constant as shown also by Doherty and Nickle[1] is

$$T_a = \frac{1}{\sigma_a} = \frac{\sqrt{x_d'x_q}}{r} \text{ in seconds}$$

$$= \frac{\sqrt{x_d'x_q}}{r} 2\pi f \text{ in radians} \quad (25)$$

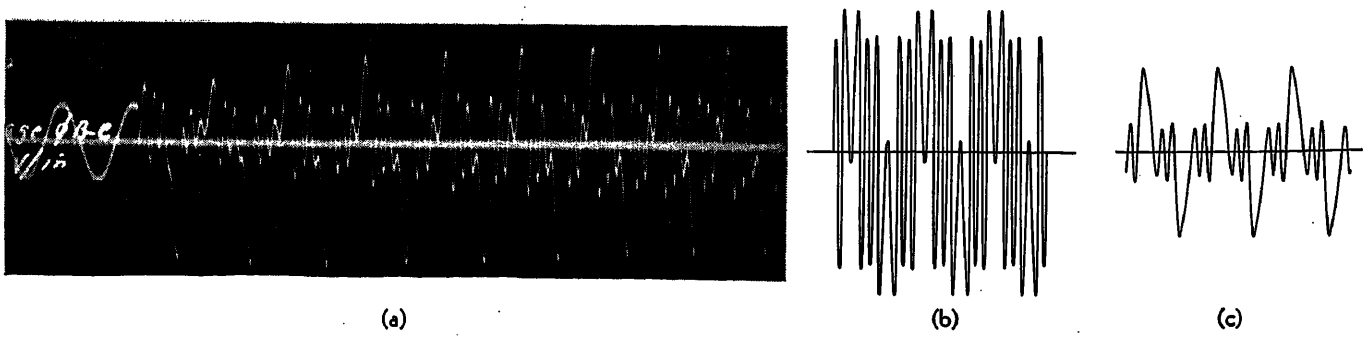
The time constant of a circuit consisting of a reactor $x_L$, capacitor $x_c$, and resistance $r$ (all in per unit) is

$$T = \frac{x_L}{2r} \text{ in seconds}$$

$$= \frac{x_L}{r} \pi f \text{ in radians} \quad (26)$$

Thus steady-state conditions in such circuit would be attained in a time equal to approximately $3T$.

For the general solution, therefore, one would expect the voltage across the capacitor obtained by the solution of 19 to exist for possibly a cycle, since the effect of resistance might not have had time to become effective in this time. This should be followed by a rather rapid change because of the disappearance of the even harmonics of 20 in accordance with $T_a$ of 25 and also the approach to the steady state solution for the odd harmonics of 20 in accordance with 26. This change should be followed by a more gradual decay in accordance with 24. The general performance outlined above is borne out by the oscillograms shown in the body of the paper, which in general show an initial transient that persists for just a few cycles, followed by a transient that lasts about a second. If the short circuit occurs out on the transmission line, the time constants $T_a$ and $T$ of equations 25 and 26 are reduced further, so that the initial transients decay still more rapidly than for faults on the terminals of the machine. The nature of the initial transient depends upon the instant during the cycle at which short circuit occurs. If $\alpha$ of 20 is equal to zero only odd harmonic voltages are applied to the circuit. In general, the excessively high voltages occur near resonance points for odd harmonics. For these values of $x_c/\sqrt{x_d'x_q}$ the initial transient delays the appearance of the crest value of voltage for about a cycle as evidenced by figures 1*e*, *f*, *k*, and *l*. For other values of $x_c/\sqrt{x_d'x_q}$, the initial transient requently results in much higher peaks during the first cycle than occurs subsequently. Illustrations of initially high peaks are offered by figures 1*a*, *b*, *c*, and *h*. For the high frequencies associated with large values of $x_c/\sqrt{x_d'x_q}$ the effective resistance becomes so high as to damp out rapidly the transients due to the high-frequency components. The character of the voltage, therefore, approaches that of the record obtained when no capacitors are connected to the machine. Compare oscillograms, figures 1*p* and *q*.



The principal virtue of a comparison of calculated and test curves of terminal voltage in a problem of this nature is the verification that no important factor has been omitted in the analysis. The rigorous solution even for the initial condition represented by equation 19 is quite involved and, after all, the initial boundary conditions set up by this case are not truly representative of the conditions met in practice. First, in practice, the machine will be under capacitive loading at the time of short circuit. However, this particular point makes little difference as evidenced by the oscillograms of figure 11 which show the effect upon the initial transients as influenced by the initial loading condition for similar short circuits. Second, of greater importance is the fact that the practical boundary condition most likely to be met is the opening of a breaker at the receiving end of a faulted line after the short circuit had been on for some time and the flux conditions within the machine had had ample time to change materially from the no-load conditions upon which the present development is premised. In view of these considerations the labor and difficulties incident to a determination of the initial transient voltages are not justified. However, the much simpler case of the quasi-steady-state solution for equation 19 in which the even harmonics of applied voltage have disappeared and the rapid transients due to the circuit constants have also disappeared, is justified. To be specific, the assumption will be made that $T_a$ of equation 25 and $T$ of equation 26 are zero and that $T_d'$ is infinitely large. The transients associated with the field winding have not had opportunity to change appreciably. This solution will now be obtained.

The solution will follow the line of successive approximations. It will be assumed that a voltage $e_n$ equal to the odd terms of the applied voltage of 19 is applied to a reactor of constant value, $(3/2)\sqrt{x_q x_d'} = x_L$, and a capacitor of impedance $(3/2)x_c$ connected in series. For this simple circuit the current $i_n'$ for each harmonic component can be obtained. Thus

$$e_n = j\frac{3}{2} K' [\epsilon^{j\theta} + 3b\epsilon^{j3\theta} + 5b^2\epsilon^{j5\theta} + \dots \text{ and } \epsilon^{-j\theta} + 3b\epsilon^{-j3\theta} + 5b^2\epsilon^{-j5\theta} + \dots] \quad (27)$$

$$x_L i_n' = \frac{1}{j}\sum_1^n Y_n E_n \epsilon^{jn\iota} = \frac{1}{j}\sum_1^n \frac{n}{\left(n^2 - \frac{3x_c}{2x_L}\right)} E_n \epsilon^{jn\iota} \quad (28)$$

where $n$ is odd integers.

(a) (b) (c)

**Figure 13. Comparison between test and calculated values of voltage**

$x_c/\sqrt{x_d' x_q} = 44.7$ (a) Test (b) Neglecting resistance (c) Including resistance

Actually the reactor, $x_L$, is not constant but varies harmonically with time. The instantaneous flux linkages, assuming that the current $i_n'$ flows, is obtained by multiplying 28 by 21 giving the quantity $x_L i_n' F(t)$. The drop, $e_L'$, across the reactor for this current is then

$$e_L' = \frac{d}{dt}\left[x_L i_n' F(t)\right] \tag{29}$$

and the drop across the condenser for the current $i_n'$ is

$$e_c' = -j\frac{3}{2}\frac{x_c}{x_L}\frac{(x_L i_n')}{n} \tag{30}$$

The sum of $e_L'$ and $e_c'$ gives the voltage necessary to force the current $i_n'$ through the capacitor and variable reactor. This sum will not equal the actual applied voltage but the excess or deficiency will be a second order quantity. Thus let

$$e - e_L' - e_c' = e' \tag{31}$$

Now let the voltage $e'$ be absorbed in the constant $x_L$ and $(3/2)x_c$ circuit and obtain a second current $i''$ through the application of 28. Assume the currents $i'$ and $i''$ flow and obtain the instantaneous flux linkages by multiplying $(x_L i' + x_L i'')$ by 21. The time differential of this quantity gives the drop, $e_L''$, across the reactor for the assumed current flow and the drop, $e_c''$, across the condenser is

$$e_c'' = \frac{3}{2}\frac{x_c}{x_L}\frac{(x_L i' + x_L i'')}{n} \tag{32}$$

As before, determine the excess or deficiency between the applied voltage $e$ and the sum of the drops $e_L''$ and $e_c''$. Thus

$$-e_L'' - e_c'' = e'' \tag{33}$$

Operate upon $e''$ as upon $e'$. By successive applications of these steps $e^n$ will become negligibly small. The desired solution is the last value of $e_c$ obtained.

This method has been applied to a number of cases, the results of which are shown in figure 12 which offers a comparison between test and calculated results. Since the calculations do not include the initial transients a rough comparison, neglecting the field transients which merely reduces the magnitude but does not affect the wave shape, may be made between the last few cycles of the oscillograms and the calculated curves. It will be observed that the results are quite close for those cases which are not near odd harmonic resonance, namely (*a*), (*c*) and (*e*). The lack of agreement of the other cases is due primarily to the assumption that resistance is neglected. Near resonance the resistance assumes great importance in limiting the current and also the voltage. Aside from affecting the magnitude of the voltage the resistance also introduces dissymmetry in the wave shape. To a lesser degree than the effect of resistance, the variation of reactance with frequency also contributes to the discrepancy between test and calculated results.

In order to verify the effect of resistance, case figure 12*e* was recalculated taking resistance into consideration by introducing a series resistance into the circuit equal to 0.05 $n$ per phase or 0.075 $n$ in the equivalent circuit. In the absence of more definite knowledge of the resistance at the higher currents and frequencies, this value of resistance cannot be regarded as more than an intelligent guess. The results of this calculation are plotted in figure 13. It will be observed that the wave shape of the calculated result including resistance, partakes of the general character of the oscillogram. The similarity is about as close as can be expected in view of the somewhat arbitrary assumption regarding the resistance. The seventh harmonic in particular is suppressed considerably as compared to the calculation in which resistance was neglected. In many of the calculations, and particularly this one, the solution converged very slowly which necessitated a large number of steps in the method of successive approximation.

# Discussions

## Of AIEE Papers—as Recommended for Publication by Technical Committees

ON THIS and the following 12 pages appear discussions submitted for publication, and approved by the technical committees, on papers presented at the sessions on instruments and measurements, education, and insulation co-ordination at the 1937 AIEE summer convention, Milwaukee, Wis., June 21–25. Authors' closures, where they have been submitted, will be found at the end of the discussion on their respective papers. Other discussion of summer convention papers will be published as it is made available.

Members anywhere are encouraged to submit written discussion of any paper published in ELECTRICAL ENGINEERING, which discussion will be reviewed by the proper committee and considered for possible publication in a subsequent issue. Discussions of papers scheduled for presentation at any AIEE meeting or convention will be closed 2 weeks after presentation. Discussions should be (1) concise; (2) restricted to the subject of the paper or papers under consideration; and (3) typewritten and submitted in triplicate to AIEE headquarters, 33 West 39th Street, New York, N. Y.

## A Suggested Course on Industrial Economics and Business Methods

**Discussion and author's closure of a paper by R. E. Hellmund published in the April 1937 issue, pages 446–54, and presented for oral discussion at the education session of the summer convention, Milwaukee, Wis., June 22, 1937.**

**A. H. Lovell** (University of Michigan, Ann Arbor): I believe the author is offering a distinct contribution to engineering economy and has outlined a very successful course of advanced grade for engineers actually in contact with manufacturing. It would appear difficult, however, to accomplish such training in an undergraduate college course because of the lack of design and manufacturing experience in the students together with their diversity of professional interest. Furthermore, there is a dearth of public costs and practical problem material available to an instructor who is not an integral member of a manufacturing organization. The University of Michigan has tried to present the fundamentals of engineering economy to its electrical students for the past 15 years using the senior course in power plants and distribution as the vehicle. This work follows 6 semester-hours of classical fundamental economics taught by our economics department. I wish to emphasize that, at present, for the college undergraduate, the field of generating stations is far richer in public engineering problem material and typical costs than is that proposed by the manufacturing industry.

**M. G. Malti** (Cornell University, Ithaca, N. Y.): I have nothing but praise for Mr. Hellmund's scholarly paper and I consider the bibliography as particularly valuable to those interested in this subject. I do however want to make a few remarks which are applicable to this as well as to all papers which recommend the inclusion of certain courses in engineering curricula.

A visitor found his host engaged in constructing a cabinet. Upon enquiring whether his host had had a course in wood work, the guest was told that the would-be carpenter had had no course in wood work but was constructing the cabinet out of plans he had acquired.

Many of us know the famous *psychologist* Doctor Thurston of Chicago. But few of us know that Doctor Thurston graduated as a *mechanical engineer* from Cornell University.

Kettering has stated that he generally tries to give a graduate a job in which he has had no previous training because the man's mind is not prejudiced by what he had learned in college.

This and similar papers, dealing with particular topics which engineering colleges should or should not teach, opens the broad question of what is the purpose of an engineering education—nay all education. To my mind the purpose of education is to develop one's ability to:

*a.* Study independently of teachers.
*b.* Synthesize isolated facts.
*c.* Generalize from fundamentals.
*d.* View facts objectively.
*e.* Visualize things.
*f.* Do original work.

Notice that nothing has been said about knowledge of facts of engineering or economics or psychology or any other branch of science. The reason is that facts are quickly forgotten. *We use facts merely as vehicles to train the mind.* Very few engineers remember how to integrate sine $x$. But the training they acquired in analysis and straight thinking from their course in mathematics remains with them to the end of their days.

These remarks should not be interpreted to mean that I am opposed to training along the lines suggested in this paper. Indeed I recognize the value of economics not only to engineers but also to all professional and business men. For this very reason I am also in favor of training in "human relations." I do maintain, however, that any engineer who has been subjected to a proper and well-balanced mental training can and should be able to read and assimilate the contents of Mr. Hellmund's bibliography merely through his own efforts and without the advantage (or perhaps the disadvantage) of a college course.

I would like to add another word regarding the economic aspects of this course. The value of such a course depends largely on the caliber of the person teaching it. If it is taught by one of our academic economists it is likely to consist either of antiquated economic theories or of mere statements of economic facts with very little emphasis placed on correlation, analysis, synthesis, and other mental processes which the student can use in solving his future economic problems. This remark is based on the reaction of our engineering students to courses now offered to engineers in economics. The teacher of such a course should be an experienced mature individual who knows the facts, who knows these facts as a part of a science, and who possesses the ability to put his science across. Persons with these qualifications in "*industrial economics*" are rare and command salaries far beyond the scale of university salaries.

In view of these facts I believe that the plan, adopted by Mr. Hellmund, of teaching this course as a part of the training that a company gives to its cadet engineers, seems to be the best solution to the problem.

**R. C. Putnam** (Case School of Applied Science, Cleveland, Ohio): Mr. Hellmund's paper gives pertinent and challenging suggestions to the teachers of electrical engineering. In this regard, I believe that it will be of interest to bring before this discussion an independent, parallel development that has been a part of the electrical engineering curriculum at Case for the past 3 years.

Briefly, this is twofold: first, a course in engineering economy given to all seniors in electrical engineering, and second, an integrated group of studies on business and engineering administration subjects which may be optioned by the senior student.

Since this second part will be discussed next week at the convention of the Society for the Promotion of Engineering Education I shall not take it up here.

The course in engineering economy is similar in aims and content to the suggested course outlined by Mr. Hellmund in this paper. The treatment, however, is somewhat different. A 3-hour course for one semester, it comes in the last of the senior year, in order to give the student all the technical background and maturity of outlook possible.

It first considers the fundamentals of engineering economy, such as the various factors involved in problems of immediate economy as contrasted to the ultimate

economy where long-range considerations are necessary, break-even points of equal economy, the economics of capacity, of replacement, and of future increased demand. This includes the study of depreciation and its various methods of computation, of sinking funds, amortization, capitalized cost, and the various other methods of comparing present out of pocket expenses of maintenance, labor, etc., with the more intangible costs of capital expenditure, either present or future.

The second part of the course is devoted to consideration and solution of problems in the generation, distribution, and application of power and in the design, manufacture, and sales of electrical apparatus. Here the problems are based on case material furnished by electrical manufacturers, public utilities, etc. Some involve an understanding of public utility rates and their underlying costs.

This may sound like a lot of material to be covered in one course, but it must be kept in mind that the object is to give the student an understanding and appreciation of the economic principles which an electrical engineer should know for the proper practice of his profession. After the fundamentals have been established, a comparatively few well chosen problems should give such a background.

As previously mentioned, this course has now been given for 3 years, and the reaction of students, alumni, and those in industry who are acquainted with the work has been most gratifying.

**E. D. Ayres** (University of Wisconsin, Madison): I have been requested to discuss Mr. Hellmund's paper in the light of the studies which I have been making concerning the teaching of business and economics to engineers. Frankly, it is a great pleasure to get this opportunity, because I believe Mr. Hellmund has brought you not just another paper, but a note which I am convinced must be sounded loud and long until the engineering educator realizes its importance.

Coming out of industry into teaching 7 years ago I was convinced then that there was something fundamentally amiss with an education which divorced engineering from its normal economic atmosphere. After 5 years of building up a comprehensive course at Wisconsin comparable to Mr. Hellmund's suggested course, and after 2 years of intensive study, analysis, and report on the subject of what should be done about teaching business and economics to engineers, I find myself with a message which I believe to be exceptionally sound and carefully considered in the light of criticism and experience.

We hear on both sides of the fence—that is both in college and in industry—that the job of the engineering college is to teach fundamentals. Nevertheless the college has for one reason or another steadily refused to accept this duty with respect to the economic considerations of engineering. As any engineer in industry will agree, the time of most engineers is taken up to a great extent with economic considerations. (See Mr. Hellmund's paper, second column, line 8, page 446, ELECTRICAL ENGINEERING, April 1937.) Why then are not these considerations just as important as other fundamental studies in engineering? The answer is decidedly that they are. But our teaching system is frankly not equipped (for a discussion of the implications of this sentence see "Treatment of Cost Aspects of Engineering in School," by Edmund D. Ayres, page 477, *Journal of Engineering Education*, February 1936) to furnish the background nor "pocket-book consciousness" so essential to efficient handling of these matters. The issue is therefore one of leaving this matter with industry where it has largely been or doing something about it in college.

It is not uncommon—but it is inconsistent for the "dyed in the wool fundamentalist" in engineering to cling tenaciously to the sound idea of "teaching fundamentals" and to cast into "outer darkness" all suggestions toward improvement in the treatment of the cost aspect of engineering yet deplore in the same breath the "hired man" status of the professional engineer. Gentlemen, there is but one solution to the dilemma, and it is in training the engineer early and often for leadership upon the firm base of an understanding of the economic and social factors which govern the world in which he must move. From the viewpoint of this broader problem the college must assume a responsibility.

The special course in adminstrative engineering, industrial engineering, and the like cannot solve the problem either. They are excellent treatments for the "commercially minded" student, but they do not reach the "backbone of our profession"—the technical engineer. These courses must weaken the engineering preparation of the student to accomplish their goal and I have ample proof that they do. To reach the technical engineer we must do a better job in his particular college curriculum or rely upon a post scholastic effort for both the treatment of the economic aspects of engineering and the generation of an ability for the engineer to express himself orally and on paper.

To put strength into any move to accomplish these ends, the start must in general be made in college. Living with this problem will force you just as it has me to state that the engineering college must accept the duty of including the fundamentals of economic considerations in the college engineering curriculum. Long study of the problem will also bring you, I believe, to the conclusion that the comprehensive survey course is the only practical solution in sight for the technical engineer. I should like to commend Mr. Hellmund's suggestion to you with all the force I can command, because I believe it now to be imperative that our profession consider well and act immediately upon these matters.

But all is not said when conclusions as to the need for this work are drawn. The most obvious answer to whether such a course as Mr. Hellmund suggests should be a general requirement is yes. The answer to whether it should come early in the engineering work is also yes—but if we insist on being realistic the answers to both of these questions must be qualified in accordance with the teaching resources of the college. Mr. Hellmund has prescribed for his course 2 hours a week for a year. Such a course can be given in that time, and its success will depend directly upon the quality of teaching. Such a brief time, however, forces the teaching quality to such difficult heights that certain practical steps must be taken if such a course is to be a practical success in the engineering college atmosphere. A course such as Mr. Hellmund has described must be taught by an engineer with a background firmly rooted in industrial practice. The teacher to handle the fundamentals of such work properly must assume the role of engineer, accountant, lawyer, and to some extent economist and salesman in turn and all at the same time. The swift transition from one topic to another must be skillfully handled or else a bewilderment in the student is created which to overcome requires a high order of interest on the part of the student (whom you must remember cannot evaluate his interest yet against a particular job in industry as a bench mark). In ordinary English such a course is forever threatened with being christened a "hodge-podge" and losing the respect of the college.

After 5 years' experience in teaching such a course I am firmly convinced that such orientation courses must have a "vehicle" to carry the breadth of material which is included. In our case accounting is used as the vehicle for the first half of the course and economic selection is used as the vehicle for the second half. I discussed this matter briefly last June at the annual meeting of the Society for the Promotion of Engineering Education and in order to conserve time here I should like to refer you to that paper. ("Graduate Work in Engineering and Economics," page 103, *Journal of Engineering Education*, October 1936.) Orientation courses of necessity are like a tramp along a range of hilltops. If a student is inattentive while you are striving to make the panorama that unfolds itself from the various hillcrests mean as much as you can, he is nevertheless quite satisfied if you can place in his basket during the trip something tangible such as an understanding of the rudiments of accounting or a grasp of the principles of economic selection. This philosophy of course results in the need for at least 3 hours per week during the school year to accomplish what Mr. Hellmund proposes to accomplish in 2. The selection of accounting as a vehicle also introduces naturally an expansion of Mr. Hellmund's course further into the financial field than he has suggested. In our case we believe this to be justified in view of the thought which I wish to bring next into this discussion and because of the existence of the third course of 2 hours a week for one half a school year called "manufacturing and production methods," required of all mechanical engineers and emphasizing in considerable detail much of the production and marketing phases included in Mr. Hellmund's course. Our 3-hour a week year course cannot be permitted to duplicate this course to the point of placing a pall upon the interest of the mechanical engineers required to take both courses. There is much more which could be said about the pedagogy and content of courses such as Mr. Hellmund has outlined but time will not permit their treatment. Before closing I am anxious to stress that Mr. Hellmund's suggestion and our practice should be but the starting point of the engineer's training in business and economics.

This thought is treated in full in a recent paper of mine entitled "The Next Step in Engineering Education" (*Wisconsin Engi-*

*neer*, page 136, April 1937; *Milwaukee Engineering*, page 9, May 1937; also promised publication in an early issue of *Mechanical Engineering*).

The guidance in economic matters afforded by the comprehensive survey course is important, but unless the profession finds some way to continue and organize this guidance, the engineer is going to fail to achieve the economic competence which can only come with a well rounded view of the operation of economic factors in society as a whole. Digging on one's own power will do it—yes—but it takes a much longer time and a consuming interest to drive the process through—and if the engineer is to stand up to the lawyer, accountant, business graduate, and politician early he must be given effective help. In advance of the ultimate 5- or 6-year curriculum which some day seems to be coming for all engineers, the dire need is for a continuation process—a floating curriculum of work which can be partly or wholly taken in either the post graduate or post scholastic period or both.

**M. S. Coover** (Iowa State College, Ames): Since a measure of responsibility for shaping one curriculum in electrical engineering rests upon me, Hellmund's suggested course on industrial economics and business methods is of more than passing interest. It is an ambitious outline including essential factors of timely importance and I concur in the opinion that some way ought to be found to include a course of instruction in the program of training commonly designed for chemical, electrical, and mechanical engineering students that would be molded around the thoughts set forth in his article.

Inasmuch as it has been my privilege to have organized and taught courses on management, the proposal strikes a receptive chord. These courses, however, were offered by the school of business and were open to seniors in both the school of business and school of engineering, thus creating the sort of tie that I think has many strong points in its favor. One of the restrictions, however, was the necessity to avoid indulging too heavily into engineering terminology and engineering processes that were little or not at all familiar to seniors in the school of business. On the other hand, a course such as Hellmund proposes for engineering students only leaves the field wide open.

To put the proposed course into a reality is not without certain obstacles, principal among which is the element of time. From certain leaders in industry and in engineering education we hear the urge to stick tenaciously to fundamentals, then teach more fundamentals, and then some more fundamentals, with no venture whatever toward specialization. The reasoning being that the employer will by special training shape the man to fit his particular organization.

From other leaders in the same 2 groups comes the urge to include cultural or broadening courses. Still from others comes the declaration that the young engineer's training is incomplete without a thorough grounding in basic principles in the sciences and including industrial economics and industrial relations. Finally there are advocates who believe that the well-rounded graduate should have a reasonably good mastery of fundamentals, a pretty clear conception of economics with all that it implies, and a fair sprinkling of cultural subjects, such as foreign language, history, government, etc. All of these proposals have my hearty endorsement, provided they do not have to be jammed into a 4-year period.

Granting that provision has been made in the curriculum for a sprinkling of elective courses and that a course in industrial economics and business methods is to be made available, best results will accrue if the instructor has had some good sound commercial seasoning so that he can teach, at least in part, on the basis of plain realities and with confidence rather than have to lean entirely upon printed matter. The instructor should be accumulating constantly from the field, and preferably in person, such data on current management problems that he shape into problems for the classroom so as to make them commensurate with the time allotted to the course. One thought to bear in mind is that the capable and interested student should be able to round out the solutions to his assignments with personal satisfaction of mind without having to devote an unreasonable amount of time on them in relation to his other equally important courses.

Personally, I cannot be enthusiastic about 2-hour courses. It is plenty long from Tuesday to Thursday and longer from Thursday to Tuesday. The plan admits of too much lost motion. More effective results, I believe could be obtained from a 4-hour credit course running for one term or one semester. It would include say 3 discussion periods of one-hour duration and one 3-hour laboratory period for analytical and layout problems. Only neat free-hand sketches of layouts would be required.

As for the course content, the chronology of presenting the material and the required amount of coverage to be made each time the course is offered, I would first have implicit confidence in the instructor employed and leave the balance of the program thoroughly flexible, so that he could constantly adjust it to current data procured and to changing economic condition. Since no single textbook could possibly give adequate coverage of course content, free use of library material should be expected of the student.

**D. F. Miner** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): Since Mr. Hellmund's paper was written, an opportunity was presented for trying out a portion of the outlined course. A 2-hour one-semester course on economics of using goods was offered for graduate credit under the University of Pittsburgh-Westinghouse plan. Forty-five men, mostly recent engineering graduates, registered, of whom 25 were taking the course for credit toward a master's degree. The subjects covered were the first half of table I in Mr. Hellmund's bibliography.

Although the lecturers were selected from the staff (chiefly engineering) of the Westinghouse company rather than from the University, care was taken to provide men whose major experience had been on the subjects covered. It was felt that the intimate knowledge of the subjects and the practical viewpoint thus presented made up for any deficiency in classroom technique. The lecture method used for many sessions, was supplemented by problems, outside reading and class discussions.

As part of the course, each student was requested to submit frank criticisms of the course both as to subject matter and manner of presentation. Practically all opinions favored the idea back of the course and stated that interesting and useful phases of the subject were covered. Some students said they had previously thought economic problems were solved by executives and they did not realize that even the young engineer must make frequent decisions requiring consideration of economic factors. Many stated they had received no training of the sort before and realized what an important bearing it had on their present and future work. Some stated they thought colleges should present similar work. Others thought they could get more out of such work given by industry after they were on the job. Possibly only a limited number of industries are in a position to organize such classes and that being the case, some general parts of the subjects will, of necessity, have to be covered by college work if it is done at all.

The course was conducted without adherence to specific details of one company's operations. Many commented on this and desired more definite information. While this may be of immediate use in their daily work, it is still considered best to cover each subject in as general terms as possible. As to teaching methods there was a definite desire for more illustrative problems and more class participation through discussions, possibly led by students. The students commented that the personal enthusiasm and specific knowledge of the lecturers vitalized the course in a way not so easily possible with recourse only to textbooks. We were gratified to observe that the students were keenly aware of the importance of industrial relations problems—that a satisfactory handling of people is necessary to the economic success of work with machines and materials.

In the autumn the second semester's work on economics of producing goods will be started and some of the ideas contributed by students will be tried out.

**R. W. Sorensen** (California Institute of Technology, Pasadena): Mr. Hellmund's authoritative advice regarding the use of some of the engineering student's time during his regular 4-year baccalaureate course for the study of things not strictly technical, such as industrial economics and business methods, is indeed timely. Having advocated and used such a program in the teaching of electrical engineers for more than 25 years, I can certify the fact that men with such training on the whole are better prepared for entry into industry than are students who have taken highly specialized technical courses without obtaining the values which are present in parallel courses involving economics and other humanities.

Of course it is quite evident to all of us that the problem is not simple and there is no clear-cut answer as to just what part of the young engineer's education shall be strictly in the field of his profession and what part shall prepare him to associate without embarrassment with his fellowmen who are not particularly interested in the technique of the mechanical aids to civilization which are in such common use today.

As a group, engineering educators have recognized the demand for a larger amount of knowledge of economic subjects on the part of some of our engineers by having in some of the engineering colleges curricula designated by the names: engineering economics, management engineering, etc. In my experience, the evils of these courses, as evidenced by the skimpiness of the engineering obtained and the tendency which they have to attract students who cannot make a satisfactory showing in the strictly technical fields, indicate that they are at least dangerous in any set of college curricula, if not inadvisable when they are undergraduate courses.

In fact, I think we should fairly generally refrain from adding to our 4-year courses more and more of the technical content of our profession, which is so rapidly developing, and should tend toward making the 4-year courses leading to the baccalaureate degree general but intensive engineering curricula which include as separate courses, some, but a distinctly limited amount, of the work outlined by Mr. Hellmund.

I am glad to note further that the paper under discussion presents material which can be used to a large extent by men teaching the strictly technical engineering courses pertaining to electrical machinery and does not of necessity require for its inclusion in an engineering curriculum the setting up of many separate courses dealing with economics only. For example, when a class is studying the technique of electrical-machinery design, it is entirely possible for the teacher to point out factors which influence design because of cost of materials, labor, test, inspection etc. Also, it is very easy to point out how designs may be modified without much sacrifice in electrical characteristics so that standard frames may be used for several machines.

My particular suggestion, therefore, would be that the teachers of engineering in discussing the design and operation of electrical machinery with students, supplement the technical phases of design and performance by discussion of the economic factors which influence the construction and operation of the machine and also by showing how the use of the machine influences the economic life of those who use it. In fact, it seems somewhat surprising to me that any teacher of electrical machinery can avoid so doing, because I recall quite distinctly the fact that one of the students in the first class in dynamo-electric machinery which I ever taught said to me one day: "Well, all of these facts are very interesting, but you seem to indicate that the final decision as to whether a machine will be built and installed and as to how it will be built is largely a matter of dollars and cents rather than electrical phenomena." That man became an outstanding sales engineer. But lest I lose caste with the technical men of my profession, may I also add that one of his classmates received a very different message from the things taught in the class and went out from the college with a desire to be a very skilled technician who reveled in the theory of the electrical circuit.

**R. E. Hellmund:** The extent of the discussion of my paper and the generally favorable reaction is very gratifying in that it definitely indicates an increasing interest in the subject on the part of the teaching profession. In some of the discussions it is pointed out that it will be difficult for the colleges to obtain suitable material for class work, particularly problems, and that it will be even more of a problem to find instructors prepared to carry on a course of this nature. It is of course true that some difficulties will be encountered in any new undertaking, but I do not feel that those arising in this particular work will be insurmountable. The only practical solution therefore seems to be to get started and to improve both the material and the teaching personnel as time goes on.

I know that a number of efforts along lines somewhat similar to those outlined in my paper have been under way at various schools, such, for example, as described by Putnam for the Case School of Applied Science, by Ayres for the University of Wisconsin, Coover for Iowa State College, Lovell for Ann Arbor, and others. The relative success and favorable reception of these efforts are in themselves evidence that something of value can be accomplished. It is quite natural that these efforts, each started independently of the other, should differ, and also that they should differ in certain respects from the course suggested in my paper. As a matter of fact, I believe that the trying out of certain variations in anything that is comparatively new is very essential for arriving at the most successful finial solution. My purpose in giving such a detailed outline was chiefly to assist those who wished to undertake some new work of this character and who might find it difficult to obtain appropriate material. In making variations from the suggested plan, however, I believe that the proposed comprehensive character of the course should not be lost sight of and that some phases of the work which have been neglected in the past in courses of this nature should be given careful consideration. As an illustration of this, the combination of courses mentioned by Professor Ayres would permit the use of much of the material outlined in my paper, but the titles of the courses in themselves do not indicate that sufficient attention will be given to such important matters as marketing, stock-keeping, obsolescence of stock, and standards. Again, the practice suggested by Professor Lovell of considering economic matters in connection with the course on the generation and distribution of power, while having certain advantages, is not likely to afford an opportunity for stressing the very important subjects just cited.

Some of the discussions bring up the question of whether the proposed course should be given during the four-year curriculum or as postgraduate work. Mr. Miner in his discussion gives a logical answer to this when he points out that since only a limited number of industries are in a position to organize classes, the work must necessarily be given in the regular college course if all of the students are to profit by it. I furthermore agree with Professor Ayres to the effect that in order to put strength into this move, the start must in general be made in college. This does not preclude the desirability of those schools located in industrial centers giving such material in a postgraduate course; in fact, plans along this line are now under way. Some of the discussions stress the fact that colleges should deal essentially with fundamentals, but it is also pointed out, and quite properly, that the fundamentals of economics are as important as other fundamentals. Professor Malti in particular points out that the principal purpose of education is to develop certain qualities and habits in the student. I myself have made similar statements too often to take any exception to this. However, even though this is very true, we must not overlook the equally true fact that engineers, like men of other professions, must have a great deal of knowledge if they are to carry on their work efficiently. It would be very foolish to ignore this fact entirely during the four-year course, and the present practice of imparting to the student as much knowledge as practically possible in addition to developing within him the qualities outlined by Professor Malti is very effectual. The only question then that can be raised is that of whether certain kinds of knowledge should best be acquired before or after graduation.

I have not commented in full on all of the discussions, but it is obvious that the various viewpoints of teachers of many years' experience, such as Professor Sorensen and others, as well as the experiences cited by Mr. Miner, should be given full consideration by those interested in the subject.

## Per-Unit Quantities

**Discussion and author's closure of a paper by Irven Travis presented for oral discussion at the education session of the summer convention, Milwaukee, Wis., June 22, 1937, and scheduled for inclusion in a special supplement to the annual TRANSACTIONS for 1937.**

**M. G. Malti:** See discussion, page 1400.

**B. R. Prentice** (General Electric Company, Schenectady, N. Y.): Mr. Travis has made a timely and valuable contribution to the literature of engineering education in his brief and clear exposition of per-unit quantities. I agree with him that per-unit representation is "confusing to the average student" and for another reason in addition to those he has given. Students are often introduced to per-unit at the same time that they take up the study of some new machine or subject, frequently, synchronous-machine theory. Added to the fresh concepts of the new theory are the novel ideas of per-unit, multiplying the confusion. Mr. Travis has aptly applied per-unit to well-known problems.

In developing the "theorem in dimensional analysis," it is tacitly assumed in equation 16 that the parameters and variables can be expressed in terms of not more than 4 fundamental dimensions, length, mass, time, and electric charge. It is then properly shown that "It is never possible to assign more than 4 independent bases." However, it is inferred that this last statement applies to physical problems generally instead of the limited class of problems covered by the tacit assumption. Obviously, if 3 or

5 fundamental dimensions had been assumed, the mathematical derivation would have resulted in a maximum of 3 or 5 independent bases, respectively. In general, pure mathematical proofs of the number of independent dimensions in other than specific problems cannot be given as dimensions are inherent physical things, and rest on experimental laws and arbitrary definitions. In one important class of problems, it is convenient and desirable to include a fifth fundamental dimension, temperature. Such problems are those involving heat flow as well as mechanical and electrical phenomena. I believe that, in such problems, the dimension temperature (or its substitute) can only be eliminated by recourse to kinetic theory which is outside the realm of most engineering problems.

The "theorem in dimensional analysis" is valuable for finding the number of independent bases and determining which specific ones are independent in any actual problem provided one knows the independent fundamental dimensions involved from physical reasoning.

**Irven Travis:** Mr. Prentice is entirely correct in his statement that the conclusions in the "theorem in dimensional analysis" apply to the limited class of problems described by the 4 fundamental dimensions; length, mass, time, and electric charge. In a preliminary draft of the paper, the theorem was set up for a system of $n$ independent dimensions; this was changed in an effort to simplify the derivation as much as possible for student consumption.

The general rule for assignment of bases is: Independent bases may be assigned to any group of quantities, providing the rank of the matrix formed by the exponents in the dimensional formulas for these quantities is equal to the number of bases to be assigned. It is evident that in the matrix described, the number of rows is equal to the number of bases, and the number of columns is equal to the number of fundamental dimensions. The greatest possible number of independent bases is, therefore, equal to the number of fundamental dimensions.

An error has been called to my attention by Mr. J. E. Hobson. In figure 2, under receiver, 10,000 kw should read 10,000 kva.

joy. The committee on education, in sponsoring these papers, has injected into the Institute an activity the need of which has long been felt by the Institute membership in general and by educators in particular.

## A New Magnetic Flux Meter

**Discussion and author's closure of a paper by George S. Smith published in the April 1937 issue, pages 441–5, and presented for oral discussion at the Instruments and measurements session of the summer convention, Milwaukee, Wis., June 22, 1937.**

**R. F. Edgar** (General Electric Company, Schenectady, N. Y.): Professor Smith's paper describes an instrument which should prove useful in many applications. Two achievements have been realized in the development. The first is the development of an instrument employing bismuth but having a zero indication which is not affected by temperature changes. Lack of this feature has been one of the biggest objections to the use of the bismuth spiral as a means of measuring magnetic field strength. The second lies in the ability of the instrument to measure flux densities in the range below 1,000 gauss.

The calibration curves of figure 3 show a very nearly linear characteristic from a full-scale value down to about 2,000 gauss. Are calibration curves for the lower ranges, say for a full scale value of 2,000 gauss, similar in shape, or do they curve to a greater extent throughout the range? Is the zero adjustment as stable for this low range as for the higher ones? What does Professor Smith consider to be the lowest range which it would be feasible to design the instrument for?

This method of measurement differs from that of using a search coil and galvanometer in that the latter is definitely directional and, in a uniform field, measures only the component perpendicular to the plane of the coil. Does the bismuth spiral exhibit any difference in its action which depends upon the direction of the magnetic field? Would the action of a straight piece of bismuth conductor be the same in a longitudinal field as in a transverse field?

**G. S. Smith:** The questions by Edgar and Sprague are quite opportune since the answers to some of them had not been discovered until after the paper had been published.

A meter just recently completed, was so made that 3 exploring bridges could be used with the same meter equipment. Table I shows the variation in design in these bridges.

Bridge number 3 was the most sensitive and was calibrated for a full-scale range of about 2,100 gausses. Bridge number 1 was calibrated for a maximum range of 22,000 gausses. It is evident that any of the bridges could be calibrated for any upper limit within the range of the calibrating equipment.

Answering Mr. Edgar's questions first, I would say that in the calibration curves for the higher ranges, the straight line portion of the curve occupies a little greater per cent of the full scale on the meter than in the lower ranges.

If an accurate zero adjustment is obtained it is very stable for all ranges on the meter. It is evident, however, that when using the lower ranges, the greater sensitivity available will cause a greater displacement from zero if any temporary resistance changes take place. Such variations can be caused by quick changes in temperature in one or more of the coils above or below the remainder. In the normal use of the meter such differences

**Figure 1. Effect of holding plane of bridge coils parallel to magnetic flux**

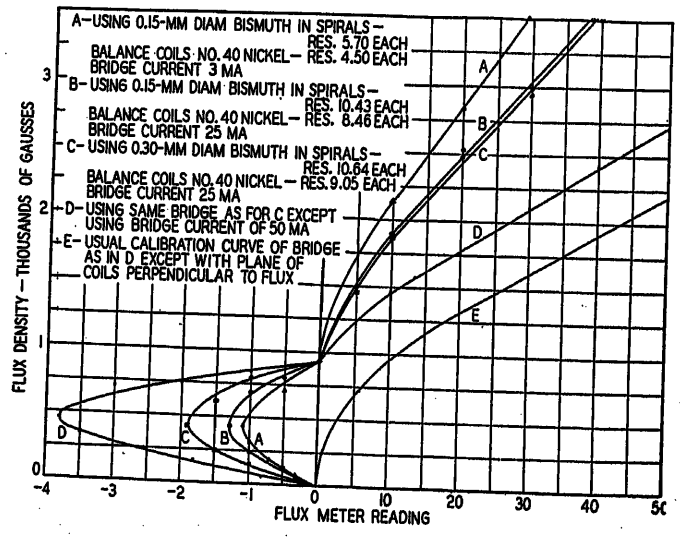

**Table I**

| | Number 1 | Number 2 | Number 3 |
|---|---|---|---|
| Diam. of bismuth wire used—millimeters | 0.15 | 0.15 | 0.30 |
| Approx. resistance of each spiral—ohms | 5.7 | 10 | 10 |
| Diameter of spiral—millimeters | 5 | 7.5 | 15 |

## Fundamental Concepts of Synchronous Machine Reactances

**Discussion of a paper by B. R. Prentice presented for oral discussion at the education session of the summer convention, Milwaukee Wis., June 22, 1937, and scheduled for inclusion in a special supplement to the annual TRANSACTIONS for 1937.**

**M. G. Malti** (Cornell University, Ithaca, N. Y.): These papers are in a class which the Institute might well foster. They are admittedly expository and contain recent developments in electrical engineering presented in a new, clear, and concise form which the student and the average engineer can read and thoroughly understand and en-

usually exist for only a few seconds, if at all, after which the true zero position of the meter is restored.

It is rather difficult to state the lowest feasible range for such an instrument. For a portable instrument, using the small inexpensive type of meters, and a bridge diameter of about one centimeter, a full scale range of about 2,000 gausses would probably be as low as could be expected. By using a more expensive meter, as the flux-reading meter, or more material in the bridge, or both, the full scale range might be reduced to 1,000 gausses or less. By using a sensitive galvanometer, in which case the meter would no longer be portable, the full scale range might be reduced well below 500 gausses. A vacuum-tube amplifier might also be used, though little has been done thus far in attemping this.

Previous researches have shown that less change in the resistance of bismuth takes place in a longitudinal field than in a transverse field. The curves *A*, *B*, *C*, and *D*, in figure 1 show the results of calibrations made when holding the plane of the spirals parallel to the magnetic field, while curve *E* is for the same bridge as used in *D* except holding the plane of the spirals perpendicular to the magnetic field. For low flux densities the readings for *A*, *B*, *C*, and *D* are negative, and for higher values displaced vertically from the usual calibration curve as in *E*. It should be noted that the scale in figure 1 is greatly magnified on the negative side. This negative effect may be due to some characteristic of the nickel wire used as balancing resistors in the bridge. Careful resistance measurements on a plain bismuth spiral placed first with its plane parallel to, and second, perpendicular to, the magnetic field, showed less change in the resistance in the first position than in the second, but showed no tendency toward a negative or lowering of the resistance at any flux density.

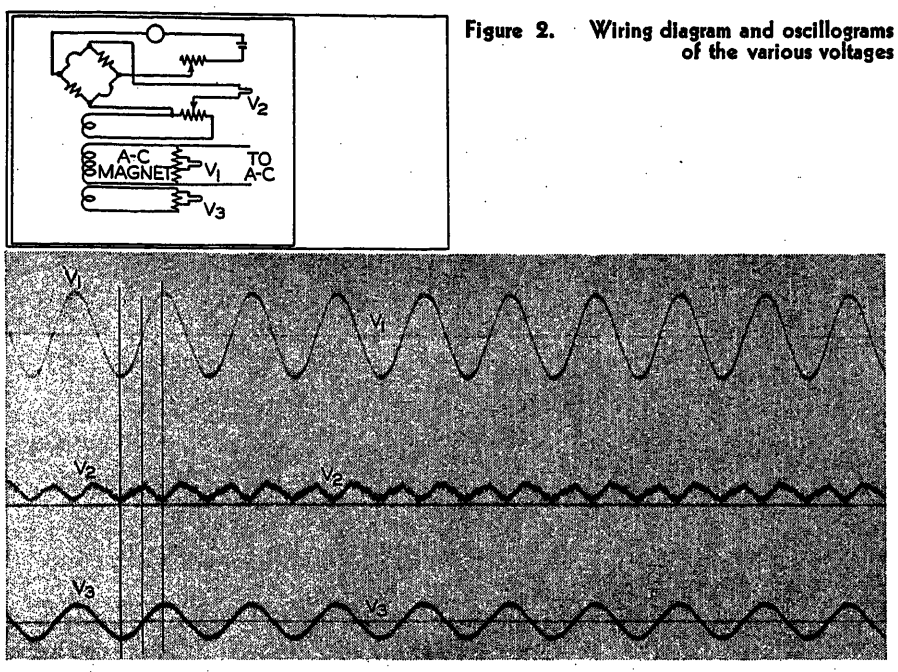

**Figure 2. Wiring diagram and oscillograms of the various voltages**

It is interesting to note that the changeover from negative to positive occurs at about the same value of flux density regardless of the size of wire or resistance used in the bismuth spirals. This might also be an indication that the negative effect is due to some characteristic of the nickel rather than the bismuth.

Mr. Sprague inquired about the use of the flux meter in alternating or transient fluxes. The bridge does give a reading for an alternating magnetic flux, but thus far too little has been done in this field to make any more definite statements.

A crude, but sensitive oscillograph vibrator was constructed and used as the flux indicator $V_2$ in the bridge circuit as shown in the wiring diagram in figure 2. Thus the $V_2$ wave in the oscillogram shows the flux variation due to an alternating magnetic field caused by the voltage shown in $V_1$. $V_3$ shows the voltage induced into a separate coil about the same field. As will be noticed in the wiring diagram, it was necessary to balance out a small component of alternating voltage induced into the bridge circuit since it apparently was not entirely noninductive in construction. Since the vibrator used was very crudely constructed, and not oil damped, it is scarcely feasible to attempt to explain the harmonics shown since they might have been due partly or wholly to other causes than flux variations.

Figure 3 shows the results of using the meter to measure the variations of the flux density in the air gaps of motors and generators. In these curves only the maximum and minimum values were measured, and the remainder of the curves sketched in. With a suitable instrument, the complete curves, accurate at every point, could be very quickly and easily obtained by photographic or curve drawing methods.

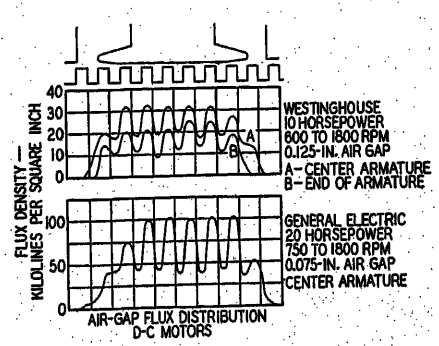

**Figure 3**

# A New High-Speed Cathode-Ray Oscillograph

**Discussion and authors' closure of a paper by H. P. Kuehni and Simon Ramo published in the June 1937 issue, pages 721–7, and presented for oral discussion at the instruments and measurements session of the summer convention, Milwaukee, Wis., June 22, 1937.**

**J. H. Hagenguth** (General Electric Company, Pittsfield, Mass.): The authors have given a very good description of the new oscillograph. One of these oscillographs has been in use in the high-voltage engineering laboratory, with which the writer has been connected, for the last year and a half. This oscillograph represents a great improvement in the oscillographic art chiefly from a mechanical point of view.

The compactness of the assembly combined with accessibility of the component parts permits easy handling of the oscillograph and provides for the least amount of trouble. The adaption of the completely sealed cathode-ray tube eliminates all delays inherent to the continuously evacuated type, resulting in a considerable saving of time. Several improvements in the tube design might be desired: First, the curvature of a d-c calibration line at the higher calibration voltages might be eliminated (see figure 4 of paper), second, the focusing of the beam might be improved, to give a more uniform and sharp definition of the beam on the front and on the tail of waves (figure 5 of paper).

Considering the low cathode excitation voltage of only 15 kv, as compared to 60 to 80 kv of the usual cold-cathode continuously evacuated oscillograph, the writing speed is excellent. At the higher rates of speed required for front-of-wave testing at 1,000 kv per microsecond or higher, the record on the film sometimes does not reproduce well on a blueprint, but the necessary data can be taken from the film directly so that the oscillograph can be used for all testing, which at present is required for high-voltage work.

The easily varied cathode-voltage supply enables the use of the oscillograph in connection with the transient analyzer for determining wave shapes for transformer impulse testing.

**Otto Ackerman** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): In the first part of their paper the authors give a very clear and interesting

review of the history of the cathode-ray oscillograph. They relate how, with the development of high-voltage metal oscillographs with internal photography, the art of measuring electrical transients has come to its height and has actually reached its limits. It was with instruments of this type that by far the biggest part of all impulse testing and research in the last 10 or 12 years has been carried out, which made the cathode-ray oscillograph an invaluable tool in science and industry. Since it is the very essence of our endeavor as engineers to obtain certain results in the simplest and most economical manner, the development on cathode-ray oscillographs has of course been continued, although types are already available which have as high a recording speed and accuracy as can be needed. It is, therefore, quite appropriate that any new appearance in this field be scrutinized as to whether it comes up to the standards in performance which the industry has already learned to expect.

One extremely important feature which has helped to make the cathode-ray oscillograph such a remarkable instrument is its instantaneous response to an external impulse. It is not clear why, in this new type, a time lag of about 20 microseconds is introduced before the timing sweep is started. Should the formation of the grid-controlled cathode beam require any such interval which practically excludes this type from the use of the recording of random phenomena?

Another feature which it appears to the writer entails many hidden difficulties, is the use of a great number of small sphere gaps. Five such sets are shown in figure 3. Their spacing can be only of the order of $^1/_{16}$ inch. They obviously need a great deal of attention for constant operation.

Whether it is the time lag in the formation of the beam or the variations in the system of small gaps, it appears to be necessary to definitely start the oscillograph before the surge generator or, in other words, start the surge generator by means of an impulse from the oscillograph.

Since the voltages available at the oscillograph circuit are comparatively low, an intermediate impulse amplifier must be added (see figure 7).

Regarding the oscillograph records themselves, the obtainable accuracy in voltage measurements is, of course, another important feature. It is partly determined by the ratio between the picture size and the width of the recording trace. Are the records as published about full size?

Of equal importance in this respect is the uniformity of deflection or calibration. The upper lines of the calibration record in figure 4 are quite definitely curved. This accentuates another problem in oscillograph design: The potentials applied to the deflecting plates influence the speed of the electrons passing between them. If the deflecting potentials are not negligible compared with the cathode voltage, the electron speed suffers changes which result in nonuniform deflections and are partly responsible for pattern distortion.

These features could be expressed in terms very much like those of speed and focal length when speaking of photographic cameras, which serve to compare their quality. If such terms were already used with cathode-ray oscillographs, they would establish some sort of rating for this type of equipment.

The writer, furthermore, likes to suggest that the apparent misprint in reference to a film speed of 500 feet per second be corrected. To unsuspicious readers, this figure might not seem extravagant with an instrument where one deals with fractions of microseconds and hundreds of kilometers per second of writing speed.

The writer finally would like to take exception to the inference on page 722, that the vacuum system on metal oscillographs need be a troublesome and unreliable feature. While it is true enough that the production of satisfactory pumping equipment and air-tight vessels requires a highly specialized technique, the reliability of the finished product cannot be doubted where porcelain solder seals by the millions and automatic pumping equipments, as for instance in mercury arc rectifiers, have proved their dependability in countless industrial applications.

**R. J. Donaldson** (Commonwealth Edison Company, Chicago, Ill.): The Commonwealth Edison Company has had one of the General Electric type *HC*-15 cathode-ray oscillographs for several months. Some of our operating experiences may be of interest to others.

In using the oscillograph with the rotary film drum, to make records of events occurring over a period of several cycles of a 60-cycle wave, it is sometimes desirable to have the cathode-ray beam stay on for an accurately predetermined time. If it is on for less time than this, the record may be incomplete, if it is on for more, there are unnecessary traces on the film.

The duration of the beam is determined by the time required for an adjustable capacitor to partially discharge through a Thyrite resistor in series with the anode circuit of a thyratron tube. Due to the temperature characteristics of this tube, it is not usually possible to be sure of the exact number of cycles the beam will be on. The duration of the beam is also affected to some extent by changing from one thyratron tube to another. It was thus desirable to have some means of determining the duration of the beam just prior to the making of an oscillographic record.

This was done indirectly by measuring the product of beam current and time, or $IT$. A capacitor was connected between the cathode-ray tube anode and the oscillograph case to which the anode is normally grounded. The potential built up on this capacitance by the beam current flowing for time $T$ is almost directly proportional to the duration of the beam. This is true where the capacitance is made sufficiently large so that the potential built up on it is very small compared with the cathode-ray tube voltage. The capacitor potential was $E = IT/C$ where $I$ is the beam current, $T$ the duration of the beam, and $C$ the capacitance in series with the tube anode. The potential on the capacitor was measured with a high-resistance d-c voltmeter. Each volt represented so many milliseconds beam duration, or so many cycles of a 60-cycle wave. If the same beam intensity and cathode-ray tube voltage were used, the meter could be calibrated directly in time or cycles duration.

For the *HC*-15 oscillograph the beam current at maximum intensity with 15 kv on the cathode-ray tube is about $^1/_5$ milliampere. The duration may be adjusted for various times up to about 20 cycles of a 60-cycle source or $^1/_3$ second. The capacitance used was 2 microfarads. This gave a value of

$$E = \frac{IT}{C} = \frac{0.0002 \times .33}{2 \times 10^{-6}} = 33 \text{ volts}$$

The voltmeter used in measuring this voltage was a microammeter in series with a 5-megohm resistor. This gave a time constant to the circuit of 10 seconds, sufficiently long to permit the meter to indicate the potential on the capacitor with fair accuracy before appreciable charge had leaked off.

A very interesting characteristic of the thyratron tube controlling the beam duration was noted while operating the oscillograph with the rotating drum film holder. In this particular test the thyratron circuit was adjusted to release the beam for a total time of about 20 cycles of a 60-cycle wave. On some of the oscillograms there were several missing sections in the wave as though the beam had been blocked for a moment and then released again. The thyratron tube can be tripped from either of 2 3-electrode spark gaps in the initiating circuit. The first gap is tripped by applying a few thousand volts to the middle tripping electrode from a 60-cycle transformer and this gap in turn trips the second gap a few microseconds later, starting the time sweep. Occasionally the 60-cycle potential on the middle electrode caused several successive sparks to the gap electrode to which the thyratron grid was connected while the beam was still released. If the impulse from these sparks was negative the beam was blocked until a positive impulse occurred releasing the beam again. This sometimes occurred several times during the 20 cycles being recorded. At first this appeared quite unusual, for the anode current in a thyratron is usually considered to be independent of grid potential after the tube is tripped. However, in an article in the December 1936 issue of ELECTRICAL ENGINEERING, Herbert J. Reich of the University of Illinois points out that the grid of a thyratron may be used to stop, as well as start, the flow of current provided the current is small.

The remedy for the interrupted beam, once the cause was found, was simple: readjust the gap to a spacing such that it will spark over only once during the recording time. Actually the solution was even more simple. When using the rotating drum the starting time can just as well be a few microseconds later and the thyratron can be tripped from the sweep circuit which never applies but one impulse. This merely involves changing a plug from one jack to another.

**W. F. Skeats** (General Electric Company, Philadelphia, Pa.): The authors mention that several multiple-element oscillographs are in use in the General Electric Company. One of these is in the circuit-breaker interrupting capacity test plant.

In this application multiple elements were desired partly to observe phenomena on the

3 poles of a 3-phase breaker and partly to observe the operation of different parts of a special circuit for determining the performance of breakers at short-circuit power beyond that available at the testing plant. The speed required was moderately, but not extremely, high, the maximum frequency anticipated being about 200,000 cycles, but on the other hand a long record was

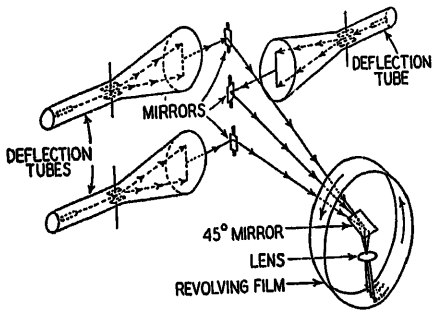

**Figure 1. Optical system of cathode-ray oscillograph**

necessary as it was desired to observe phenomena occurring two or three hundredths of a second apart. It was also desirable to have records available promptly after each operation with a minimum of delay before the instrument would be ready for another record.

Many of the unique features of the design will be evident from a diagram of the optical system which is shown in figure 1. Three sealed glass deflecting tubes with fluorescent screens are used. These deflect the beam in one dimension only giving a deflection proportional to the quantity being measured. A lens focuses the light from these

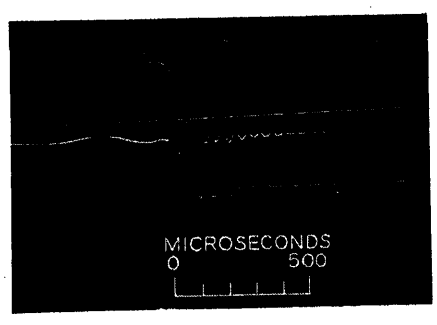

**Figure 2. Section of cathode-ray oscillogram**

screens upon a film mounted on the inside of a rotating drum. One mirror is used to make the necessary bend in the light beams on the inside of the drum, and in order to obtain compactness of the field of vision and reduce its size 2 deflecting tubes are placed on one side and one on the other of a central axis, individual mirrors being placed on this axis to reflect the three light beams into the same plane. These latter also provide an adjustment to line up the 3 spots with respect to each other on the film.

The film was placed on the inside of the drum in order to make high peripheral speeds available without the introduction of awkward clamping means or the possibility of breaking or loosening of the film on account of expansion resulting from its own centrifugal stresses.

The drum is 12 inches in diameter, and rotates at a maximum speed of 10,000 rpm. This gives a time scale of 6 microseconds per millimeter, stretching out one cycle of a 200,000-cycle wave over 0.8 millimeter. With a reduction of about 5 to 1 in the optical system, a sharply defined curve is obtained which can easily be read at this spacing.

Figure 2 shows part of a record obtained with this oscillograph indicating the voltages attendant upon the interruption of the last two phases of a 3-phase-to-ground fault on an ungrounded generator. The upper and lower traces are the voltages across the 2 poles of the breaker clearing at the time of the record and the center trace shows the voltage induced the phase which had cleared previously.

**A. T. Sinks** (General Electric Company, Lynn, Mass.): We have had in our laboratory at the West Lynn Works for about 8 months a cathode-ray oscillograph of the type described in this article. During this period the oscillograph has been in use at least 50 per cent of the time testing instrument transformers and has been of great value to us in designing transformers for higher impulse-voltage strengths.

I do not mean to imply that impulse testing was made possible only by this new oscillograph, as before its advent we made impulse tests for a number of years using the old type of oscillograph in which the film was inside the tube, and for the most part results obtained with this instrument were very satisfactory and we made quite valuable improvements in instrument transformer design on the basis of these results.

However, in our work, the new oscillograph has demonstrated its superiority over the old type in a number of ways. In the first place, with the new design, as the authors state, the time of pumping a vacuum and any question of having the right vacuum after replacing the film is eliminated. In the second place, one can see the wave at the same time a picture is taken. On the old type this was not possible and there was no way of knowing what happened when a surge was recorded on the film until the film was developed. When, as frequently occurs, one wishes to know what has happened before going further, it is obviously very much more convenient to be able to have some knowledge of what occurred without waiting to develop films and disassemble apparatus.

Another point of interest in the new oscillograph is that we have found the calibration of the cathode-ray tube to be very constant and consistent.

Since the whole apparatus including trip circuits and calibrating devices is co-ordinated in one design and made in one unit the operation of the apparatus is simplified.

When all is taken into account, we, therefore, feel that the new oscillograph design represents a valuable advance in the art.

**P. R. Benedict** (nonmember; Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The development of this new self-contained, portable oscillograph is a noteworthy contribution to the technique of impulse testing. This device fills a need for a laboratory instrument which bridges the gap between the low-voltage cathode-ray oscillograph and the cold-cathode 60-kv constant-beam oscillograph. Two features of the instrument which are new are the simultaneous viewing and recording arrangement and the cathode beam initiating unit. In regard to the cathode-beam initiating system I would like to ask the authors what beam current is used in the tube. How is it measured for the short time the tube is in operation?

In recent years, more and more stress has been laid on front-of-the-wave testing and it has been necessary to improve the existing cold-cathode instruments. All reliable impulse data must be sealed from recordings of actual impulses applied to the test piece. Oscillations on the test wave tend to decrease the density of the trace and make suitable recording difficult. In order to get readable, reliable records, all spurious oscillations must be eliminated from the system. It has been my experience that nearly all spurious oscillations come from poor grounding arrangements. Grounding the test generator at only one point helps a great deal. All divider cables should be grounded at the generator ground. A copper-braid sheath over the lead sheath of the divider cable also helps to reduce superimposed oscillations on recorded test waves. The divider cable sheath should be insulated from ground over its whole length. Short heavy ground connections should be used at both ends of the cable. The authors show no damping resistors in the timing plate leads to the cathode ray tube. Such resistors placed at the timing plates help to cut out inductive pickup from the voltage leads and other parts of the oscillograph system. A resistance value of 3,000 ohms is about right. The timing calibration should be made with the resistors in. The unit described by the authors is very well shielded as the oscillograms show.

The oscillograph tube of this article uses electrostatic concentration methods for producing an intense beam. The cold-cathode instruments are much harder to focus in this way but satisfactory progress has been made in this country and in Europe. Field control at the cathode seems to offer the best solution of concentrating the beam electrostatically. The use of a magnetic concentrating coil between the cathode and anode, so placed that the beam is focused on the anode hole, 0.025 inches in diameter, improves the recording speed materially. I would like to ask the authors what the recorded trace width is. In high voltage it is imperative that the beam be intense but narrow. Assuming a trace width of 0.1 inch, and a deflection of 2 inches, the trace width is 5 per cent of the recorded voltage. Such a wide beam introduces errors in scaling oscillograms and while the recording speed may be increased by using a large diameter spot, a trace width of about 0.040 inches is desirable.

What is the actual deflection in inches of the records of figure 5 and figure 6? Also, what is the approximate voltage of figure 6? In high-voltage recording it is desirable to use about a 3-inch voltage deflection for satisfactory accuracy. A time deflection of about $2\frac{1}{2}$ inches per microsecond is also necessary for wave-front testing. The testing of lightning arresters and all apparatus

at short time to flashover values require such deflections for satisfactory scaling, especially where time to flashover curves are desirable.

The rotating-drum type of camera can also be applied to the cold-cathode type instrument and the loss of time due to repumping after each film is more than offset by the excellence of the record. In the modern high-voltage beam oscillograph 8 to 10 minutes are consumed in pumping to working vacuum after a film change. When taking time to break down curves, using roll film, as many as 150 records are taken on a 6-exposure film. The cold-cathode instruments may be used to cover the range of 10,000 microseconds to the shortest times obtainable in surge-generator circuits. Calibrations are permanent and accurate to about 1 per cent. While the authors state the writing speed of 10 inches per microsecond, the requirements of wave-front testing and short time to breakdown phenomena are such that 50 inches per microsecond is desirable in an instrument used for the collection of pertinent impulse data.

**H. P. Kuehni and Simon Ramo:** Mr. Ackerman's comments and questions about the new cathode-ray oscillograph are indeed very interesting and also highly pertinent and the authors welcome this opportunity to discuss here briefly some of the details which might not have been sufficiently clearly brought out in the paper.

The second, third, and fourth paragraphs of Mr. Ackerman's discussion are quite closely related from the point of view of the oscillograph design features and they may be answered as follows.

In order to serve as a fundamental background for the general discussion, it may perhaps be well here to state the basic requirements which guided the design of the new oscillograph.

(*a*). The oscillograph must satisfy practical impulse testing requirements. It must be capable of recording standard impulse testing waves.

(*b*). The oscillograph records shall show a portion of the sweep (zero line) before the wave record begins so as to obtain a full wave record. This result is to be obtained without the use of delay cables. Therefore, this feature makes it necessary to initiate the oscillograph sweep before the appearance of the impulse wave at the oscillograph deflection plates.

(*c*). In view of (*b*) above, the oscillograph shall include means for initiating an impulse generator and shall include proper timing equipment to release the cathode-ray beam, to start the sweep and to initiate the impulse generator at the correct time.

(*d*). The oscillograph shall also be capable of recording random phenomena whereby the cathode-ray beam and sweep are initiated by an incoming voltage impulse. For this application the response must take place within a fraction of one microsecond.

For reasons of economy and also to arrive at a compact design the internal oscillograph initiating circuits were limited to 7.5 kv with respect to ground, and 3 electrode gaps were selected to initiate these circuits. It is quite natural that Mr. Ackerman should question the reliability of low-voltage gaps of this kind and the authors share his skepticism in a general way. However, by the use of effective artifices the performance of these gaps was rendered reliable in service without necessitating undue critical gap adjustment. Tests have shown that small gaps of the type used may be made to perform very uniformly by ultraviolet light irradiation. The necessary gap irradiation is obtained from an auxiliary circuit and it is the main function of the primary initiating circuit, which is tripped by the 60-cycle transformer and push-button shown in figure 3, to supply the needed ultraviolet light at its spark gaps. As figure 2 shows, these gaps are mounted very close to the sweep-initiating-unit gaps. The time performance of the auxiliary circuit gaps obviously need not be accurate.

Inasmuch as a primary initiating circuit was used, it was decided to initiate with it also the cathode-ray beam. The time delay of approximately 20 microseconds, introduced between the primary initiating circuit and the sweep circuit, was quite arbitrary and was admittedly originally introduced to give the thyratron tube and the cathode-ray tube ample time to establish the cathode-ray beam before the initiation of the sweep. However, it was soon found that this precaution was quite unnecessary, because the cathode-ray beam could be initiated in a small fraction of a microsecond by applying a sharp voltage impulse to the thyratron grid. Nevertheless, the resistance between *M* and the sweep circuit midsphere was retained to prevent a voltage impulse of large magnitude at *M* and the thyratron grid *L* when the sweep circuit midsphere is tripped by an incoming voltage impulse applied at *O* as shown in figure 7. Also, this method of primary beam initiation provided a convenient means of initiating the cathode-ray beam in rapid succession for beam focusing purposes without having to wait 20 or 30 seconds for the sweep-circuit capacitors to charge through a high resistance.

Referring to the diagrams of figure 3 and figure 7, when the oscillograph is to be used for recording random phenomena, provisions are made, by means of a flexible lead and plug, to connect the thyratron grid lead at *O* of the sweep circuit instead of at *M* of the primary initiating circuit. In this case the incoming voltage impulse through *Q* is then used to initiate the gaps of the sweep circuit and the cathode-ray beam. By using a fairly large incoming momentary voltage impulse of, say, 50 kv, which is usually readily available in this type of recording, ultraviolet gap irradiation as described above is now not needed. Thus, it is not necessary to start the oscillograph before the surge generator. However, it is generally advisable to do so, whenever the impulse generator initiation is under control, as is the case in impulse testing and when a complete wave record is desired without the use of an artificial delay of the arrival of the voltage wave to be recorded.

In figure 7 there is shown between the oscillograph and the impulse generator an intermediate initiating circuit which was used, as pointed out by Mr. Ackerman, to amplify the 7.5 kv output from the oscillograph. Since the publication of the paper a simple inexpensive air-core type of transformer was developed to take the place of this unit, whereby the voltage of 7.5 kv is transformed into a voltage of 70 or 80 kv suitable for initiating directly the impulse generator. The polarity can easily be changed by simply reversing the output leads. This method has proved to be highly successful and precision timing was obtained.

The performance of this type of oscillograph in impulse testing work has been excellent and as many as 120 consecutive impulse records per day were taken.

The curvature of the d-c calibrating lines shown in figure 4 is due to the spherical curvature of the fluorescent tube screen. By simply superimposing the oscillograph wave records on this calibration chart this slight curvature should be of no consequence as far as the measurements of deflection amplitudes are concerned.

The oscillograph reproductions shown in figures 4 and 5 are approximately $\frac{1}{2}$ full size and the original films are $3\frac{1}{4}$ by $4\frac{1}{4}$ inches.

Mr. F. R. Benedict's interesting comments relating to the technique of building impulse testing circuits free from spurious oscillations agrees well with our own laboratory experience.

The exact magnitude of the beam current in the cathode-ray tube has not been measured. However, test evidence obtained by observing, by means of a cathode-ray oscillograph, the voltage drop across a suitable resistor in the cathode circuit indicated that the beam current is approximately one milliampere when the beam intensity control is adjusted to maximum at zero control grid bias.

The width of the recorded trace of the records shown in figure 5 is approximately $\frac{3}{32}$ inch where it is widest. The width depends on the cathode spot motion, it being somewhat larger when the cathode spot is moving slowly. However, the high-vacuum type of cathode-ray tube with electrostatic control grids leads itself to a very fine beam-intensity control.

The amplitude deflection of the records shown in figure 5 is approximately $1\frac{1}{2}$ inches. The records of figure 6 were taken with a small camera giving a record about $\frac{1}{5}$ full size. In our laboratory we project these records for analysis on a graduated screen by means of an enlarging camera with excellent results.

Mr. R. J. Donaldson's discussion refers to the use of the new oscillograph for rotating film drum recording. In the transient recording with stationary film and cathode beam sweep, the slight erratic shut off of the thyratron tube is, of course, of no consequence because the cathode-ray beam is already swept off the screen when the beam is finally shut off. Mr. Donaldson has made a very interesting contribution in the form of his current times time number of cycle indicator.

The authors wish to rectify here an omission in the bibliography of the paper and attention is here called to an excellent paper by Messrs. K. B. McEachron and E. J. Wade entitled "Study of Time Lag of the Needle Gap" published in the AIEE TRANSACTIONS, volume 44, pages 832–42, June 1925. This paper is one of the earliest describing the application of the high-voltage internal-photography cathode-ray oscillograph to practical electrical engineering problems.

# Sixty-Cycle Calibration of the 50-Centimeter Sphere Gap

**Discussion and authors' closure of a paper by C. S. Sprague and G. Gold published in the May 1937 issue, pages 594–6, and presented for oral discussion at the insulation co-ordination session of the summer convention, Milwaukee, Wis., June 22, 1937.**

J. R. Meador (General Electric Company, Pittsfield, Mass.): The authors have described what appears to be a very practical method of measuring high a-c voltages that lends itself particularly well to calibration purposes.

While making 60-cycle spark-over tests on grounded sphere gaps ("Calibration of the Sphere Gap," J. R. Meador. ELECTRICAL ENGINEERING, June 1934) in 1933 at Pittsfield, the writer had occasion to take a few check points on a 50-centimeter isolated sphere gap. The results were not published at that time due to the small number of spacings tested and to the fact that only one size of sphere was used. Since the calibration points checked the values in Standards Number 4 to within 2 per cent to 3 per cent, there did not appear to be an urgent need for further investigation. The more complete investigation conducted by Messrs. Sprague and Gold seems to indicate that a slight revision of Standards Number 4 for isolated spheres would be desirable.

The calibration points that were obtained by the writer are compared in table I with those for nonirradiated spheres given by the authors and with Standards Number 4.

It will be noted that the maximum difference between the Pittsfield points and those

**Table I**

| Sphere-Gap Spacing (Centimeters) | Spark-Over Voltage (Kilovolts Crest) Nonirradiated | | |
|---|---|---|---|
| | Meador | Sprague and Gold | Standards No. 4 |
| 10 | 262 | 266 | 265 |
| 15 | 370 | 374 | 381 |
| 20 | 468 | 465 | 475 |
| 25 | 555 | 545 | 557 |
| 30 | 626 | 624 | 632 |
| 40 | 755 | 764 | |

of the authors is 1.8 per cent which is very good agreement for measurements of this nature.

My voltage measurements were made with a voltmeter coil and vacuum tube crest voltmeter. I fully agree with the authors that the crest voltmeter is a very satisfactory and convenient instrument for this type of voltage measurement.

P. H. McAuley: (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The authors have made another contribution to the improvement in sphere-gap calibrations on which a great deal of work has been done in the last few years. It is gratifying to note that their values for the nonirradiated ungrounded gap are mostly within 2 per cent of the present standard values.

In a general way the method of measurements used appears satisfactory when the precautions mentioned in the paper are taken. Much depends on the vacuum-tube crest voltmeter, for which, unfortunately, no details are given. Some Westinghouse testing transformers are equipped with a crest voltmeter operating on the bushing charging current. The same principle was used by Fortescue and Farnsworth in their original fundamental calibration of the sphere gap. It is perhaps appropriate to describe the method briefly at this time.

If $Q$ is the charge of a condenser at a crest voltage $E$, 2 $Q$ is the change in charge from a voltage $+E$ to $-E$. The change per cycle is 4 $Q$. The average current, disregarding sign, is the charge flowing in coulombs per second. If $C$ is the capacity of the condensers, the average current is $4\ Qf = 4\ CEf$, where $f$ is the frequency. To obtain an indication of the average current, the condenser charging current is rectified and measured with a D'Arsonval type of meter. Either a mechanical or a thermionic type rectifier may be used.

This furnishes a simple and reliable method of measuring high voltages, especially when the testing transformer is equipped with condenser bushings. It is of course customary to check the crest voltmeter against the sphere gap to guard against changes in capacity with voltage. Once its performance is determined, however, it can be relied upon for most testing conditions. It is sensitive to disturbances in the high voltage circuit and, with a thermionic rectifier, trouble may develop in tests causing high frequencies or excessive harmonics. Methods of overcoming these troubles have been described (D. F. Miner, *Electric Journal*, December 1925). An outstanding feature of this crest voltmeter is that it is independent of the load on the testing transformer.

It would be interesting to have the authors report the results of their study of the effect of voltage on the capacities of the bushings. It has been our experience that the effective capacity increases as much as 2 per cent at the higher voltages.

C. S. Sprague and G. Gold: In response to Mr. McAuley's request for more detailed information on the crest voltmeter employed by the authors, the following brief description will be given here.

The working range of the crest voltmeter proper is about 30 volt crest, hence its use on high voltages requires a capacitance divider of known ratio, of which the condenser-type bushing conveniently supplies the high-voltage capacitor. Low alternating voltage up to 30 volts is supplied to the grid circuit of a vacuum tube having a sufficiently high input impedance so as not to disturb the potentiometer ratio. Full-wave rectification of the a-c component is provided by a duodiode in the plate circuit, by which means 2 series condensers, connected as in a voltage-doubler circuit, are each ultimately (after several cycles) charged to a d-c potential proportional to the crest value of the voltage applied to the grids. This d-c potential is in turn applied to the grids of a d-c push-pull amplifier with a milliammeter and a differential shunt in its output circuit, the reading of this milliammeter being a function of the crest voltage of the alternating wave applied to the instrument.

The instrument proper has no inherent calibration but it can be accurately calibrated at low voltage. It is not sensitive to occasional high frequencies but indicates the average value of the applied crest voltage over a number of cycles. Since the indications depend upon the change in plate current, that is, upon the slope of the $E_g$-$I_g$ curve, and not upon the absolute values of plate current, the instrument is insensitive to changes in the supply voltage.

With proper design, the instrument responds quickly to any change in the applied voltage and is independent of wave shape and sustained harmonics or tooth ripples, even under the most extreme conditions.

When first built the possibility of error due to changes in the characteristics of the vacuum tubes was considered. However, with operation of the vacuum tubes well within their ratings, no trouble of this sort has been experienced in continued operation over periods of a year or more. As with the rectified charging current type of crest voltmeter, the device when used with a capacitance potentiometer can be occasionally checked against a sphere gap. Also with either type of crest voltmeter the capacitance of the condenser-type bushing should be accurately known.

With regard to the change in capacitance of the bushing with voltage the authors are glad to present the following data. The bushings were designed for operation at 300 kv effective. The capacitance was constant up to approximately 55 per cent of this value. Between 55 per cent and 100 per cent the capacitance increased, at first slowly, then more rapidly, ultimately showing a total increase of approximately 1.1 per cent.

Mr. Meador's discussion presents comparative data showing a close check between Mr. Meador's results and those of the authors for nonirradiated spheres. Such a check is always gratifying to both parties.

# Basic Impulse Insulation Levels

**Closure of a paper by the EEI-NEMA joint committee on system insulation co-ordination, published in the June 1937 issue, pages 711–12, and presented for oral discussion at the insulation co-ordination session of the summer convention, Milwaukee, Wis., June 25, 1937. Previous discussion of this paper appeared in the October 1937 issue, page 1298.**

Philip Sporn: Setting up insulation levels on a voltage basis has laid the foundation for carrying on the more important work of the Joint Committee in specifying the insulation strength of all classes of equipment in the established levels and in allocating these levels to the normal system of voltages.

General agreement on the basic levels as indicated in table I, was reached, of course, only after certain compromises and minor

differences of opinion. As mentioned by Mr. Foote and as pointed out in the report, consideration should be given to increasing the 100-kv impulse level in the 15-kv class. The apparent lack of agreement here appears to be due to the fact that the 100-kv level really corresponds to the 13.8-kv class (if such were recognized) as can be readily shown by plotting the basic levels against the rated voltage classification. It is planned to give this matter further consideration in the committee.

The heading of column 1 of table I "maximum rated voltage classification" was the heading agreed upon by the committee. As Mr. Foote points out, however, it may be desirable to change this wording if there is confusion, as there apparently is, interpreting the present heading to mean that basic impulse levels are definitely tied up only with system voltages having numerical values given in column 1. A way of clearing up this entire matter might well be by referring to the different basic impulse insulation levels by letters or numbers independent of the system voltage on which they may be applied.

This report covers the progress so far made by the committee in the insulation co-ordination problem. There is still a great deal of work to be done and this may perhaps constitute the major part. If it had been found possible to recount in detail the various discussions within the committee prior to adoption of these levels, a clearer understanding of how the values given in table I were arrived at would be evident. As Mr. Foote points out, "the basic levels are intended to be reference levels." This appears to clearly define what these basic levels are supposed to represent.

Mr. Vogel assumes that these levels are "purely arbitrary since the foundation which is the voltage level which can be maintained by protective equipment is lacking." In other words, a basic level is a benchmark on which all other insulation and protective equipment in the system is based. If I understand Mr. Vogel's comments correctly, he believes that protective devices should be standardized and that transformers and other equipment should be based on the performance of the protective device. Further, if Mr. Vogel's remarks are understood correctly, he would design a piece of apparatus self-protected and place it in a system with the firm belief that the apparatus would perform satisfactorily regardless of whether the system itself functions as a unit or not. This is exactly the type of thing that insulation co-ordination is intended to prevent, that is, the throwing together of a mass of equipment such as power transformers, circuit breakers, instrument transformers, bus insulators, etc., each made to the pet ideas of the individual designer or manufacturer as regards construction and protection without consideration of the broad point of view of the protection of the system as a whole when this equipment is installed and has to work as a unit. Experiencing situations of this kind frequently and in actual practice has been one of the principal factors in giving insulation co-ordination the large amount of attention and consideration that it has been given up to the present time and is still receiving.

It makes little difference where the basic level is set; whether at the protective device, the transformer, the station entrance, or elsewhere, but once set, the problem becomes one of selecting and using margins between the various steps of insulation where these steps are desirable and economically justified. The bases on which these insulation levels were selected were distinctly not arbitrary, but have been co-ordinated so far as information has been available with present-day protective devices. A close study of data published in papers by Messrs. Foote and North and Messrs. Sporn and Gross show clearly that consideration has been given to the protective devices at present available.

As the work of the committee progresses in "carrying out its purpose and scope in:

1. Specification of insulation strengths, and
2. Allocation of insulation levels as mentioned in the paper"

it is believed that the co-ordination of insulation on a power system will become much less difficult. The proper use of the principles of insulation co-ordination will, it is confidently believed, result in more economical power systems.

## Insulation Strength of Transformers

**Closure of a report of the transformer subcommittee of the AIEE committee on electrical machinery published in the June 1937 issue, pages 749–54, and presented for oral discussion at the insulation co-ordination session of the summer convention, Milwaukee, Wis., June 25, 1937. Previous discussion of this report appeared in the October 1937 issue, pages 1297–8.**

**I. W. Gross:** This paper was intended to give a historical record of the development of the insulation strength of transformers, particularly the impulse strength. In so doing, it was desirable to recount the various steps which were taken in setting up impulse tests on transformers, and in conclusion, the paper gave impulse-test values (tables II and III) of transformer and bushings, together with a brief outline of the proposed method of test where it differed from past procedure.

The fact that a question has arisen since the report was published (as pointed out by Mr. Montsinger) regarding the magnitude of test voltages seems to indicate that perhaps the report was not entirely clear in this respect. It may be well, therefore, to briefly summarize the entire aspect of impulse tests on transformers.

It is recognized that a transformer in service may be subjected to 3 different types of impulses, namely, a full wave, a wave chopped on the tail, and a wave chopped on the front. Impulse testing of transformers has developed today to the point where it is perfectly safe and practical to impose on a transformer in the factory tests with full waves and waves chopped on the tail. Some work has been done and still is in progress on applying tests with waves chopped on the front, that is, front-of-wave tests. The standard wave used to test transformers is the $1\frac{1}{2} \times 40$ wave, and it, of course, may either be of a positive or negative polarity. Since the first of the year when the test procedure was clarified by speaking of impulse-test voltages in terms of their crest value instead of inches of gap—which, of course, was only a test device—the recommended impulse test on transformers boils down to the application of full-wave and chopped-wave applications. Following past procedure, the test now recommended calls for 2 chopped waves but of equal value followed by the full-wave test. The magnitude of impulse-test voltages correspond, in general, to the voltages permitted by the test gaps formerly specified. In accord with action taken by the transformer subcommittee at its meeting in Milwaukee, June 25, it was agreed that the test values indicated in table II of the paper should be recommended, subject to the changes indicated in Mr. Montsinger's discussion above, namely, that distribution transformers in the 15-kv class be subject to a full-wave test of 95 kv and a chopped wave test of 110 kv. Likewise, it was agreed at that meeting to recommend the bushing characteristics given in table III with the change that the 15-kv-class bushing impulse flashover value be changed from 110 kv to 105 kv. These tables II and III with the 3 changes indicated are the latest recommendations of the committee on magnitudes of impulse tests on transformers and their bushings, the sequence of application being 2 chopped waves of equal magnitude followed by one full wave.

While the above 3 changes in voltage values in the 15-kv class from those given in tables II and III have been agreed upon, there is still a feeling by some of the members of the committee that the values should be retained as given in the table. However, since entire agreement could not be obtained it was felt better to go along with the lower tentative values in the 15-kv class than hold up the entire matter until agreement had been reached.

Considerable discussion has developed over the gaps on transformer bushings. Mr. North points out that "gaps mounted directly on bushings are very undesirable and should be discontinued." Others in the industry have voiced the same sentiment, and it seems quite likely that the development of standards for transformers, together with their bushings, will eliminate the bushing gap entirely. It seems perfectly clear that the matter of setting up and testing insulation strength of transformers is one thing and the protection of that transformer is another, whether it be protected by gaps, lightning arresters, or some other device. The 2 problems are, of course, interrelated and should be co-ordinated.

It has been clearly brought out in the discussions that there is a hazard in mounting gaps on bushings due to the possibility, and in many cases almost certainty, that the power arc, which will develop over the surface of the bushing when these gaps break down, will damage the bushing. Actual experience has shown this to be true. It is believed, however, that where gaps are used in connection with transformer protection, they should not be close enough to the bushing to result in a destructive arc on the bushing itself.

Answering Mr. North's question regarding the definition of "a directly grounded circuit," which appeared in the 1930 AIEE Transformer Standards. As near as can be determined at the present time, this definition was set up to accomplish several things;

first, to make it impossible to consider a system's neutral solidly grounded if it had a small grounding bank or potential transformer bank Y-connected with the neutral physically attached to ground. Another point considered appears to have been that the system neutral would be held sufficiently close to ground potential to consider the system grounded if the requirements set up in the footnote were followed. Further, it was considered improbable that troublesome oscillations would be set up in the system due to transient voltages resulting from arcing grounds if the procedure outlined in the footnote were followed in defining the system as directly mounted or isolated.

## Application of Arresters and the Selection of Insulation Levels

**Authors' closure of a paper by J. H. Foote and J. R. North published in the June 1937 issue, pages 677–82, and presented for oral discussion at the insulation co-ordination session of the summer convention, Milwaukee, Wis., June 25, 1937. Previous discussion of this paper appeared in the October 1937 issue, pages 1293–6.**

J. H. Foote and J. R. North: The large amount of constructive discussion of these papers is appreciated and we are especially glad to have the various phases of this matter of insulation co-ordination amplified by others who have been working actively with the problem.

We would like to call attention to 2 corrections which should be made in our paper. On page 680, item (*b*) should not mention fault resistance and should read: "(*b*). The ratio of zero-sequence impedance (including neutral impedance) to positive-sequence impedance...."

The ratio $Z_0/Z_1$ is indicative to some extent of the effectiveness of the neutral grounding. The voltage during fault conditions from sound phase to ground may range from less than $E_n$ to more than $E$ line-to-line, depending upon the netural conditions. In many cases, it will be found that an 80 per cent arrester may be used if the ratio $Z_0/Z_1$ is equal to 2 or less and that a 70 per cent arrester may be used if this ratio is equal to one or less; however, it should be distinctly understood that this approximation of the arrester rating is only a general "rule of thumb."

Mr. Halperin has questioned the necessity of the arrester voltage rating being at least 10 per cent above the calculated maximum sound phase voltage-to-ground. The rating of an arrester is based upon the 60-cycle voltage at which it will cut off after discharge. Considering the possibility of a line-to-ground fault coincidental with the surge, it was felt that arresters should have a margin of at least 10 per cent above any such voltage which it might be called upon to clear. The ability of an arrester to clear itself is influenced to some extent by the voltage recovery rate and experience has indicated that the performance is much better on systems having a moderate ratio of reactance to resistance. Then, too, arresters in the lower-voltage classes tend to have a higher factor of safety than those in the higher-voltage classes.

Messrs. Piepho, Ross, and Vogel have inquired as to the characteristics of present day arresters when discharging currents above 5,000 amperes. The value of 5,000 amperes was used in the paper since comparable data regarding the performance of different types of arresters was available at this current value but not generally at the higher values of discharge current. Practically, this is not of great moment since the voltage across the arresters during discharge does not increase lineally with increasing discharging current. The characteristic curve is a logarithmic exponential function and the voltage across one design of arrester during discharge of 20,000 amperes is only approximately 15 per cent higher than that at 5,000 amperes. While arresters of different designs have differing characteristics at high discharge rates, it is generally held that currents much in excess of 5,000 amperes can be discharged before the voltage drop across the arrester reaches the basic impulse insulation level. We are highly sympathetic to the plea for comparable manufacturers' data of arrester performance characteristics at higher values of discharge current and it is to be hoped that this information will be made generally available in the near future. Similar data should also be made generally available regarding the performance characteristics of older designs of arresters and arresters which may have deteriorated in service.

The adequacy of the value of one kv per circuit foot assumed for the short-time potential gradient has been questioned. This value is equivalent to an incoming wave having a front of 1,000 kv per microsecond and without reflection. In particular cases, the assumption of higher values may be necessary but it has generally been felt that one kv per foot represented a reasonably average value considering the actual lengths of circuit feet, circuit connections, and surge conditions as found in practice.

Mr. Sels has discussed the matter of insulation steps and the relative importance of different types of insulation. The relative insulation values of bus insulators, transformer bushings, etc., as given in the figures in the paper, were intended to merely illustrate certain existing insulation levels and were specifically not intended to represent necessary marginal steps between different types of insulation. Fundamentally, it seems to us that there are only 2 major steps of margins required in insulation co-ordination. First, the margin between the performance of the surge protective device under the conditions as assumed and the surge insulation level of the weakest or most important class of equipment; second, the margin between the maximum dynamic voltage-to-ground and the lowest low-frequency flashover or puncture value of insulation under the worst condition of dirt and moisture. Marginal requirements are matters of experience and economics. Transformers have generally been taken as having the limiting minimum insulation strength because of the cost involved and because preferred practice is to place the arresters or other surge protective devices as closely as possible to the transformers. Bushings and insulators have generally been selected with higher impulse insulation strengths because of the relatively small additional cost involved and due to the fact that they are subjected to dirt and moisture and in addition are often located many circuit feet from the protective device.

We fully agree with Mr. Sels that the margins should generally be greater than 10 per cent between the protective device and the apparatus. Furthermore, in our opinion, the margins should properly be expressed in terms of "( ) kv + ( ) per cent" rather than strictly on a percentage basis over the range of voltage characteristics normally considered from the distribution voltage to the highest transmission voltages. It is not apparent that marginal steps are particularly necessary between classes of apparatus in a given basic insulation level except to insure that under the worst conditions assumed for specific classes of apparatus the insulation strength will be in excess of the basic insulation level requirements.

## Insulation Co-ordination

**Authors' closure of a paper by Philip Sporn and I. W. Gross published in the June 1937 issue, pages 715–20, and presented for oral discussion at the insulation co-ordination session of the summer convention, Milwaukee, Wis., June 25, 1937. Previous discussion of this paper appeared in the October 1937 issue, pages 1296–7.**

Philip Sporn and I. W. Gross: It has been some 7 years since the subject of insulation co-ordination has been present in an organized and comprehensive manner and thoroughly discussed, as has been done in this group of papers. The extensive discussions which the papers have brought forth show not only that the subject is very much alive but also give the electrical industry an opportunity to observe what has been done during recent years in the development of thinking on co-ordination, the thoughts behind the development, and the progress made in its application.

The question of establishing margins between different types of apparatus, to obtain co-ordination, is an important one and has been discussed from several points of view. It is particularly interesting to know what some of the operating companies are doing in arriving at these margins. Mr. Sels, for example, is allowing 30 per cent margin between lightning arresters and transformers as he feels that margins of 10 per cent are not adequate. Mr. Foote's analysis of margins between arresters and transformers is extremely interesting as it brings out some of the variables which have to be considered in arriving at and recommending insulation margins. The practice of Mr. Sels' company in making the transformer the strongest piece of equipment in the station, with the bus itself graded lower, is, as pointed out, exactly opposite to that of our company. Situations of this kind show clearly the need for establishing classes of insulation levels so that they may be adapted to the individual needs and practices of the various users. Certainly at the present time no one can say that either one of these practices is right and the other wrong; and for the conditions met within

service it may be that each of these practices, although exactly opposite in principle, is economically sound in application.

Mr. Vogel has mentioned the self-protected transformer in the distribution-voltage class where protective devices are built into the transformer itself. This, of course, is similar to the practice of some companies today in locating lightning arresters directly on the transformer tank, a practice which we started as early as 1928. The question immediately arises, therefore, if distribution transformers are to be equipped with protective devices, why should not power transformers also be so equipped? This would mean that power transformers might be supplied complete with lightning arresters attached thereto, as standard equipment.

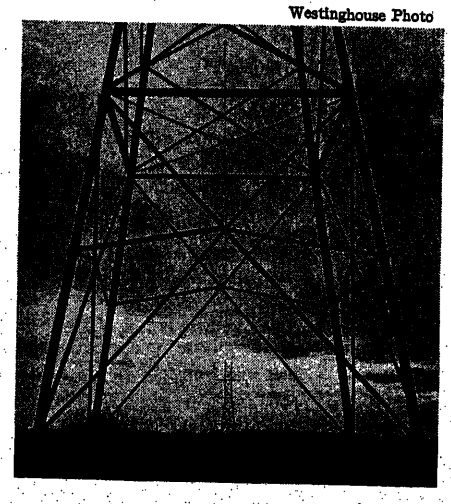
In connection with the impulse testing of transformers it has been our practice in recent years to not only equip power transformers with lightning arresters placed directly on the transformer make but also to impulse test practically all of these larger transformers. In addition to the standard impulse tests which have been developed during the past few years we require an additional impulse test on the entire unit including the arrester. That is, an impulse is applied to the transformer with the lightning arrester connected to it. The purpose of such a test is to observe the voltage characteristics permitted on the transformer by the lightning arresters under conditions simulating as nearly as possible actual field conditions. Impulse test voltages which would rise to something in the order of 3 times the magnitude permitted by the transformer test code, if the arrester were not present, have been applied to transformers in combination with arresters, the rate of voltage rise in some cases being considerably in excess of 1,000 kv per microsecond.

In addition to testing the impulse strength of the transformer itself under commercial conditions we are strongly in favor of this practice in applying a severe impulse to the transformer equipped with a lightning arrester as the installation will actually be made in the field. We would suggest that some thought be given in our technical committees in setting up the standard procedure for applying impulse tests to transformers equipped with lightning arresters.

A great deal of the discussion has apparently centered around the possibility of obtaining 100 per cent protection against impulses. We wish to refer again to that part of our paper which states the problem of "insulation co-ordination" centers around economy. This means that working out the problem of protecting equipment, while technically we may be able to protect apparatus practically 100 per cent against breakdown from impulse, it may not be the economical thing to do, and therefore we face the possibility of an occasional failure under severe impulse conditions rather than build into the apparatus itself insulation strength and into the protective device sufficient protection to eliminate failure for almost any conceivable type of impulse.

It is believed that, with the work which has already been done, and the field experience which is now being accumulated, we are fast collecting a store of information which will make this insulation co-ordination problem much simpler to handle in the future, giving us a set-up finally where it will be possible to predict the operating results of applying these principles with a considerable degree of accuracy.

## Application of Spill Gaps and Selection of Insulation Levels



**Authors' closure of a paper by H. L. Melvin and R. E. Pierce published in the June 1937 issue, pages 689–94, and presented for oral discussion at the insulation co-ordination session of the summer convention, Milwaukee, Wis., June 25, 1937. Previous discussion of this paper appeared in the October 1937 issue, pages 1290–3.**

**H. L. Melvin and R. E. Pierce:** In the discussion by Messrs. Foote and North the criticism as to the use of the term "level" as being applicable to a spill gap is well taken. It is perhaps unfortunate that the term "insulation levels" was ever applied to gaps and insulators in view of the many later attempts to picture these insulation levels as fixed or uniform values of voltage regardless of time. The origin of the term was of course closely associated with the idea of defining insulation levels in terms of "inches of rod gap."

The authors believe that the experience cited justifies the first conclusion in the paper, namely, that "spill gaps are effective as a means of establishing and co-ordinating insulation levels on lines and stations, and affording dependable protection to equipment and insulation, against failure from lightning." It is of course brought out in the paper that spill gap settings and equipment insulation strengths must be properly co-ordinated. Also instances are cited where spill gaps were set too wide to protect equipment probably in the short time zone.

The wide range of gap settings used for the same operating voltage in different locations is more the result of different methods and stages of experimentation with gap settings under service conditions rather than of calculations or complete tests to determine minimum practicable gap settings. It is therefore, doubtful if detailed explanatory data on such items as insulation strengths of apparatus and system sequence impedances would be pertinent for most of the situations cited. For the one 110-kv substation in Louisiana, however, where definite and more complete tests were carried out to determine the minimum gap settings permissible, the 110-kv system neutral is effectively grounded and the ratio of zero-sequence impedance to positive-sequence impedance is in the order of from 0.7 to 1.0 under most operating conditions. Experience has shown that designers' estimates of the impulse insulation strength of specific transformer units have been gradually lowered over a period of years as additional failures have occurred and more has been learned regarding the co-ordination of the design of the complicated insulation structure within a transformer.

Westinghouse Photo

The experience of the South Texas Company with the use of fused spill gaps as described by Mr. M. H. Lovelady is of decided interest and is further confirmation of the authors' second conclusion, namely, that minimum permissible spill gap settings are less than those previously considered possible.

With reference to table I in the paper, showing the operating record of spill gaps in Texas, it is understood that the only means used to determine whether or not these gaps operated was by periodic visual inspection.

Mr. Rorden raised the question as to whether experience indicates that most insulation failures are associated with a single severe surge, such as a direct stroke, or if there are a fair percentage of failures that occur with strokes of lesser magnitude and current, such as traveling waves, also Mr. Ross inquires if experience indicates the relative destructive effect of switching surges, induced surges, and direct strokes. The authors believe experience has fairly definitely shown that direct strokes are the only real concern as far as destruction of equipment from impulse voltages is concerned, and that the destructive effect of switching surges and induced surges are fully guarded against if the design of equipment and its protection from direct strokes is adequate. However, there are so few instances of insulation failures in which all of the facts are known that it is probably more a matter of opinion that most insulation failures are associated with a single severe direct stroke nearby, rather than from direct strokes to the line at some distance, which appear at the substation as traveling waves.

Answering the other question by Mr. Ross, the authors have no definite test data relative to the wave shape of switching surges. However, it is also our opinion that many, if not all, switching surges have characteristics intermediate between 60-cycle voltages and relatively slow rate of rise impulse voltages.

Answering the questions raised by Mr. McEachron, the fused gaps used on the 110-kv system discussed on page 691 were rated 8 amperes. The repeater type fuse operates in from 15 to 30 cycles. There are, of course, plain back-up rod gaps used in connection with all of the repeater fused gaps, having slightly higher settings, which prevent loss of protection during the interval required for the repeater fuses to come into position. Where permanent installations are made of several fused gaps in multiple, the loss of even the difference in degree of protection between the fused and back-up gaps is prevented until all fuses have operated.

## Of Institute and Related Activities

# Important Developments in Publication Policy Announced

By I. Melville Stein, Chairman AIEE Publication Committee

TO MEET the definitely expressed wishes of the Institute's membership for a broader publication service, the AIEE publication committee has been studying publication policies during the past year or so.

An initial step in this direction was taken, upon the committee's recommendation, in January of this year when the board of directors approved an additional appropriation for the publication in ELECTRICAL ENGINEERING of more articles of broad general interest during the remainder of the appropriation year ending September 30, 1937. Since that time, the publication committee has continued its study of publication and related policies with a view toward improving still further the value of the Institute's publications to the membership. To assist the committee in better determining and meeting the wishes of the membership, the subject was discussed at some length at the conference of officers, delegates, and members held during the Institute's 1937 summer convention in Milwaukee, Wis. The AIEE technical program committee also has studied the situation as it affects the work of that committee, and has made certain recommendations.

As an outgrowth of these various deliberations the publication committee has completed plans for some important developments in publication policy and procedure, which were approved by the board of directors at its meeting on October 28, 1937. These developments are outlined in the following paragraphs.

The policy of including in each issue of ELECTRICAL ENGINEERING a substantial number of articles of broad general interest will be continued, and it is expected that the changes in policy just adopted will make possible an appreciable improvement in this section.

Advance copies of all papers approved by the technical program committee for national conventions and District meetings will be provided for the use of the technical program committee and the convenience of others interested. These advance copies will be in the form of reproduced manuscripts of accepted papers, these manuscripts being subject to revision before final printing. They will be available at headquarters or at the registration desk at meetings or conventions at a price of 5¢ each; by mail the price will be 10¢ each. ELECTRICAL ENGINEERING regularly will carry announcements of advance copies as they become available.

Technical program papers will be published in a segregated section of ELECTRICAL ENGINEERING after they have been presented and finally reviewed (instead of before presentation as at present), so that the approved discussions can be correlated and published with their respective papers. Some highly technical papers that are considered to be of limited interest will be abstracted in ELECTRICAL ENGINEERING and will not appear there in full. (Such papers will be published in full in the TRANSACTIONS.) For the present it is contemplated that approximately two-thirds of the regularly approved technical program papers will be published in full in this segregated section of ELECTRICAL ENGINEERING.

The TRANSACTIONS will include only finally reviewed papers and correlated discussions approved by the technical program committee, but all formal papers presented on the technical programs at national meetings and those approved by the technical program committee for presentation at District meetings will be included except in rare special cases.

The publication committee believes that these modifications in policy and procedure should result in an improved publication service to the membership, and in a reduction of the time elapsing between the submission of a technical paper manuscript and its presentation at a national convention or District meeting. The new policy will be made effective with the January 1938 issue of ELECTRICAL ENGINEERING.

Comments and criticisms will be sincerely appreciated by the publication committee.

# 1938 International Management Congress

The Seventh International Management Congress will be held at Washington, D. C., September 19 to 23, 1938, under the auspices of the International Committee of Scientific Management (CIOS), of which Lord Leverhulme of Great Britain is president. Authorities on industrial and commercial management from about 40 countries are expected to attend. An American Congress Council has been formed with Willis H. Booth, honorary president of the International Chamber of Commerce, as chairman, to sponsor the gathering.

Discussions of the latest developments in management and the social and economic aspects of management, based upon more than 200 papers selected competitively from experts all over the world, will comprise the congress. Six sections, convening simultaneously, will deal with management problems in production, administration, distribution, personnel or labor relations, agriculture, and the home. Leaders in business are expected to take part in the discussions, together with invited governmental representatives. Extensive tours for foreign visitors through the plants and offices of industrial and commercial establishments, noted for their application of scientific management, are planned.

The congress will be under the direction of the National Management Council of the United States of America, affiliate of the international committee. It is composed of the following organizations: American Management Association, The American Society of Mechanical Engineers, The Association of Consulting Management Engineers, International City Managers Association, Life Office Management Association, National Office Management Association, Personnel Research Federation, and Society for the Advancement of Management. A co-ordinating committee, of which W. L. Batt, president of SKF Industries, Inc., and past-president of ASME, is chairman, has been formed with the following officers: *vice-chairmen*—Harry Arthur Hopf, William H. Gesell, Thomas R. Jones, Henry P. Kendall; *treasurer*—Charles G. Smith; *general secretary*—John J. Furia. Sectional chairmen include James O. McKinsey, for administration, Ralph E. Flanders for production, Leon C. Stowell for distribution, W. W. Kincaid for agriculture, and Marie M. Meloney for the home. American Engineering Council's executive committee, on the request of the co-ordinating committee, has authorized the secretary of AEC, F. M. Feiker (M'34), to serve as Washington secretary of the congress.

Previous congresses have been held at Prague (1924), Brussels (1925), Rome (1927), Paris (1929), Amsterdam (1932), and London (1935).

**New NEMA Bulletins.** The National Electrical Manufacturers Association has issued 2 new publications: (1) INDUSTRIAL CONTROL STANDARDS, publication number 37–44; and (2) INSTRUCTIONS FOR CARE AND OPERATION OF TRANSFORMERS, publication number 37–46. The first bulletin is a revision of a previous publication on the same subject, and the second contains instructions for the care of both distribution and power transformers. Copies of these pamphlets may be obtained from the headquarters of the National Electrical Manufacturers Association, 155 East 44th Street, New York, N. Y.

# Industrial and Other Topics Feature Busy Sessions at Akron—Students Take Active Part

SUPPORTED by an unusual variety of inspection trips to many different types of industrial plants, there was a very effective industrial flavor to the general meeting of the AIEE Middle Eastern District held in Akron, Ohio, October 13–15, inclusive. About a third of the 23 papers on the program dealt with problems of an industrial nature in which electrical engineers are directly interested through the development, application, or operation of a wide variety of machinery and control equipment. Also afforded a place on the program were timely papers and discussions concerning such topics as radio interference, transportation, electrical machinery, electronics, and power transmission.

This was the ninth District meeting to be held by the Middle Eastern District, and the first since 1932. Other meetings that have been held by the District are (attendance indicated in parentheses): Washington, D. C., January 1925 (212); Cleveland, O., March 1926 (430); Bethlehem, Pa., April 1927 (400); Baltimore, Md., April 1928 (400); Cincinnati, O., March 1929 (270); Philadelphia, Pa., October 1930 (500); Pittsburgh, Pa., April 1931 (500); Baltimore, Md., October 1932 (240).

Chairman A. O. Austin of the Akron Section opened the initial session, introducing Mayor Lee D. Schroy who welcomed the visitors and outlined some of the local features that he deemed to be of interest to engineers. In responding to Mayor Schroy Vice-President I. Melville Stein cited the fact that 3 of the renowned pioneers in the electrical industry were born in Ohio: Theodore N. Vail, Thomas A. Edison, and Charles F. Brush.

Presiding at the various technical sessions were: I. Melville Stein, vice-president from District 2 and past chairman (1927–28) of the Philadelphia Section; Russell Krammes, past-chairman (1931–32) of the Akron Section; A. M. MacCutcheon, past-chairman of the Cleveland Section (1920–21), one time director (1928–32), and past-president (1936–37); J. R. Martin, Cleveland; G. R. Fink, Philadelphia; F. W. Funk, Akron.

Doctor W. E. Wickenden, president of Case School of Applied Science, and past-chairman (1936–37) of the Cleveland Section presided and acted as toastmaster at the concluding banquet, where President W. H. Harrison spoke briefly prior to the introduction of the guest speaker, Commander C. E. Rosendahl. To Harold L. Brouse (A'32) electrical engineer, B. F. Goodrich Company, and chairman of the general committee for the Akron meeting, special tribute was paid by Toastmaster Wickenden and all those assembled. Confined for some time by illness, Mr. Brouse was a listener-in on the program through the medium of a microphone pick-up and a special direct wire. R. A. Hudson (A'30) efficiency engineer with Goodyear Tire and Rubber Company, was credited with effective "pinch-hitting" for Mr. Brouse.

**Analysis of Registration at Akron Meeting**

| Classification | Location: Akron | District No. 2* | Other Districts | Totals |
|---|---|---|---|---|
| Members | 30 | 165 | 35 | 230 |
| Students | 6 | 125 | 1 | 132 |
| Men Guests | 7 | 40 | 7 | 54 |
| Women Guests | 12 | 32 | 4 | 48 |
| Totals | 55 | 362 | 47 | 464 |

* Outside of Akron Section

## Radio Interference

On the increasingly important subject of radio interference, one formal published paper and 2 informal papers prepared especially for the Akron meeting were presented and actively discussed:

A Review of Radio Interference Investigation, Frank Sanford (A'28, M'34) and Willard Weise; both are employed by the Cincinnati Gas and Electric Company (published, October issue pages 1248–52).

Notes on Radio Interference, Grover Lapp (A'22), chief engineer for the Lapp Insulator Company, Inc., LeRoy, N. Y. (not published).

Radio Disturbance Measurements, W. S. Jennens and C. J. Miller, Jr., Barberton, Ohio, electrical engineers; both are employed in the Ohio Insulator Company Division of the Ohio Brass Company (not published).

Brief review of the subject was given by Messrs. Sanford and Weise who described radio interference elimination as "essentially the co-ordination of this use of electricity with its other uses for light, heat, power, and transportation, in order that the growth of each may not be restricted by the requirements of the other," and who consider as practical an approach to the problem similar to the effective approach to the problem of inductive co-ordination with reference to wire communication. Effective co-operative control measures experimentally developed in Cincinnati were briefly described.

G. W. Lapp analyzed conditions contributing to radio interference, with particular reference to transmission line insulators, and to the various methods now being followed on modern power systems for control or elimination. He pointed out that at least one by-product of interference control that is of direct value to the operating utility has been the discovery and elimination of points of incipient failure. In discussing radio characteristics of insulators he stressed the continuing importance of field tests to supplement laboratory tests and developments, considering the variation in contamination of atmosphere in different localities. He emphasized the fact that "considerable information is now available from actual cases, so that insulators can be specified with confidence to meet unusual types of severe conditions," and concluded that "the problems of satisfactory freedom from radio interference on insulators have been met as the needs have appeared and in such a way that future demands can be taken care of as they arrive."

Messrs. Jennens and Miller called attention to the method outlined by the National Electrical Manufacturers' Association for measuring radio interference on high-voltage insulators, describing it as "probably the most satisfactory method now available for laboratory use"; they stated—that this method "probably will be used by most of the insulator manufacturers, and eventually radio interference data will be correlated between the various laboratories." They pointed out, however, that before the NEMA method can be used to determine radio interference, it is necessary to correlate the microvolts across the insulator as measured by the NEMA method with the field strength of radio interference that the insulator will create when used on a transmission line. They gave various correlation data and described testing equipment and methods used.

## Mine Ventilation

"Improvements in Mine Ventilation" were described by Doctor Theodore Troller of the Guggenheim Airship Institute. As indicative of the train of beneficial development resulting from well-organized basic research, Doctor Troller described several noteworthy advances in equipment and technique of mine ventilation that have grown directly from the fruits of research originally directed toward aeronautical problems.

Doctor Troller outlined briefly the peculiar requirements of mine ventilation, citing it as typical relatively low-pressure high-quantity (20,000 to 300,000 cubic feet per minute) service, and one where notable improvements in fans have been made and more may be expected. He cited the case of one coal company where the electric power bill for mine ventilation amounts to as much as $150,000 per year, pointing out that in such a case each one per cent improvement in the efficiency of fan or related electrical equipment meant a reduction of $1,500 per year in the ventilation power bill. He reported the modern trend toward the use of propeller type fans because of their adaptability to the peculiar and varying requirements of mine ventilation, stating that "maximum efficiencies of 80 to 85 per cent can be combined with a power characteristic having the maximum power required at or near the point of maximum efficiency." He stated further that "in a few years the propeller type fan should be developed from the laboratory state to practical installation so that 90 per cent efficiency will be a regular feature, and its weight and size further reduced by about 30 per cent."

## Industrial Switchgear

"The Advance in Industrial Switchgear" was treated at some length by V. L. Cox

(A'28) of the switchgear division, General Electric Company, Philadelphia, Pa., emphasizing the necessity for continuing advance in the development of switchgear to meet the ever more complex and rigorous requirements of modern industry. Mr. Cox traced the steps followed in laying out electrical equipment for the modern plant. He described and illustrated numerous varieties of factory-built and assembled equipment which in many cases includes the complete complement of related auxiliary, control, and metering devices.

### Rubber Industry

The rubber industry came in for its share of consideration in 2 papers; the first was "Electrical Applications in Rubber Mills," by John Grotzinger (A'24), chief electrical engineer, and R. S. Ferguson and W. A. Brown of the Goodyear Tire and Rubber Company, Akron. Mr. Grotzinger and his co-authors presented a general outline of the major processes of a manufacturing plant producing rubber tires and tubes, and described the more important items of equipment used. They listed the principal power requirements for a typical plant and described methods of pre-determining energy requirements and maximum demands for plants of any capacity. Opportunities for generating power from process steam were briefly reviewed, and evidence furnished indicated that fully 50 per cent of energy requirements could be met in such a manner. (Figures given indicated a power requirement of about 0.55 kva per tire for plants capable of producing 10,000 or more tires per day, whereas a plant having a capacity of 300 tires would require about 2.2 kva per tire.)

"Recent Developments of Electrical Equipment for the Rubber Industry" were discussed by C. W. Drake (M'21) industrial sales engineer, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. Supplementing the previously mentioned paper which covered the matter of applications, Mr. Drake discussed the engineering and related problems involved in the development of electrical equipment to meet the peculiar requirements of the rubber industry.

In this discussion Mr. Drake covered 2-speed motors for Banbury mixers, and dynamic-braking starters for synchronous-motor mill-line drive. The motors discussed were synchronous machines rated at 600–1,200 or 450–900 rpm, and they were discussed in connection with various related control and protective equipment. Under the subject of dynamic-braking starters, he described and illustrated new assemblies or arrangements of equipment intended to be "of special value in connection with the present trend toward enclosed or cubicle-type equipment and the mounting of such control in remote locations," covering recent developments of several combinations of electrically operated circuit breakers "to provide forward and reverse operation with dynamic braking, performing the same functions as older types of control, but having numerous advantages from the standpoint of installation, maintenance, and especially compactness."

### Iron and Steel Industry

An insight into some of the electrical and related problems in the many ramifications of the iron and steel industry was given through the medium of 3 descriptive papers, all of which were published in the September issue:

Some High Lights in the Use of Electricity in Steel Mills, E. G. Fox (M'20), Freyn Engineering Company, Chicago, Ill.

Carbon Brushes for Steel Mill Equipment, W. C. Kalb (M'15), advertising department, carbon sales division, National Carbon Company, Cleveland, Ohio.

Tension Measurement and Control in Cold Strip Rolling, C. M. Hathaway (A'29), and F. Mohler, mechanical engineers, general engineering laboratory, General Electric Company, Schenectady, N. Y.

In addition to describing some of the more interesting features of steel mill electrification, Mr. Fox pointed out that approximately one-tenth of the investment in the American steel industry is in electric plants, and that the power consumption of steel mills is increasing; that about two-thirds of this power is generated within the plants, but that there is a tendency toward an increased purchase of power. He mentioned also that electric melting furnaces supply a small but growing increment of total steel production; that high-frequency heating is finding some uses; that new types of electric furnaces are being installed for heat treating and annealing operations.

Messrs. Hathaway and Mohler described a device called a "tensiometer" designed for the measurement of the tension in steel strips during rolling in a cold-rolling mill, and for the indication of any difference in tension between the 2 edges of the strip. They reported that "the tensiometer can function in connection with auxiliary control equipment for the automatic maintenance of the total tension to any desired value."

Mr. Kalb discussed problems associated with brush application on commutating types of equipment in the iron and steel industry, in relation to type of equipment and conditions encountered in service; discussed also a newly defined measure of brush performance, termed "commutation factor" which "provides an improved basis for control of the performance characteristics of brushes." He mentioned also the development of electrographitic grades designed to prevent the formation of troublesome surface film on commutators exposed to the contaminating atmospheric conditions frequently encountered in steel-mill applications.

### Steam Turbines

"Some Recent Applications of Steam Turbines in Industrial Plants Showing Upward Trend in Pressures and Temperatures" were described by K. S. Kramer of the South Philadelphia Works of the Westinghouse Electric and Manufacturing Company. Concerned primarily with problems incident to industrial plants where the requirements of steam for processing purposes are of prime importance, Mr. Kramer described typical installations, pointing out that the wide diversity in requirements for process steam had led turbine manufacturers for the past 10 or 15 years to build industrial turbines to special order. He reported that both condensing and noncondensing turbines have "been built for extraction of steam nonautomatically at one or more pressures, and automatically at one or two pressures in addition to nonautomatic extraction. Turbines have been built for induction as well as extraction of steam and, in some cases, extraction at one pressure and induction at another. Inlet pressures may be as low as several pounds; in some instances turbines were supplied with inlet steam at 2 pressures. Most turbines can be designed for initial operation with low pressures and temperatures, and later by minor changes made suitable for efficient operation with much higher pressures and temperatures."

### Railway Electrification

Two different problems incident to railway electrification were covered in papers presented:

The Design and Test of a High-Speed High-Interrupting - Capacity Railway Circuit Breaker, W. F. Skeats (M'36), and H. E. Strang (A'28), both of the General Electric Company, Philadelphia, Pa.

Pennsylvania Railroad Electrification, H. C. Griffith (M'35), electrical engineer, Pennsylvania Railroad Company, Philadelphia, Pa.

Mr. Skeats described and illustrated a circuit breaker designed for 25-cycle 1,500-ampere 15-kv normal service and capable of interrupting a fault current of 65,000 amperes with an over-all short-circuit duration of one cycle. He reported that "being intended for railway trolley service, which is rather severe from the standpoint of frequency of short-circuit operation, it is expected to handle 50 short-circuit operations without internal inspection or change of oil...this breaker operates upon the impulse principle." A spring-driven system forces a blast of oil through a special passageway which causes the oil to sweep directly across the arc path, a departure in design from the earlier breakers which used a "radial" blast of oil. Mr. Skeats described test methods and results.

Mr. Griffith described the scope and character of the main-line electrification project now being actively prosecuted by the Pennsylvania Railroad. Electrified lines now in operation, including the trackage used for suburban service, covers 373 miles of line, involving 1,343 miles of electrified track between New York and Washington, and from Philadelphia to Paoli, Pa., on the main line west. The project now

## Future AIEE Meetings

**Winter Convention**
New York, N. Y., January 24–28, 1938

**North Eastern District Meeting**
Pittsfield, Mass., Spring 1938

**Summer Convention**
Washington, D. C., June 20–24, 1938

**Pacific Coast Convention**
Portland, Ore., date to be determined

**Southern District Meeting**
Miami, Fla., Fall 1938

under way will complete the main-line electrification from Paoli through Lancaster to Harrisburg for passenger service, and various main freight lines east of Harrisburg. This new work will add to the Pennsylvania system some 315 miles of electrified line involving some 773 miles of track. Mr. Griffith reported that "upon completion of the new work, the Pennsylvania Railroad system will have a total of 2,677 miles of electrified track, or 41 per cent of the total electrically operated standard railroad trackage in the entire United States."

### Electrical Machinery

"Single-Phase Induction-Motor Performance" was discussed in mathematical terms by A. F. Puchstein (A'20, M'27) and T. C. Lloyd (A'31) respectively chief engineer and development engineer, Robbins and Myers, Inc., Springfield, Ohio. This paper was published in full in the October issue. In discussing their subject at Akron, the authors reported: "In a search for labor saving methods for predicting the pull-out torque (or its equivalent, the number of primary-winding turns) and the performance curves of the single-phase induction motor from design-sheet data with satisfactory precision, it became necessary to examine as much of the existing literature as could be found" (the work of 25 or more writers on the subject since 1895), and stated that "the present paper was an attempt to reduce greatly the labor of numerical application, while maintaining the accuracy within the limits dictated by modern practice."

"Recent Trends in the Design of Power Transformers" were described and illustrated in some detail by L. H. Hill (A'22, M'29) engineer-in-charge, transformer division, Allis-Chalmers Manufacturing Company, Milwaukee, Wis. Mr. Hill stated that "during the past 15 years ... there have been more changes in power transformer design than in all the years prior to that time." He called attention to such modern trends as improved internal mechanical construction, designing for impulse strength and the related tendency to use dielectric flux control to reduce internal oscillation, and reported a trend toward "increased use of tap changing under load both in straight transformers and in regulating units, increased use of phase-angle control under load, forced-air-blast equipment, inert-gas protection, design for oiltightness, use of large 3-phase units, and multiwinding units."

### Electronics

"Low-Current Ignitors" were described by A. H. Toepfer (A'31) research engineer, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. He outlined briefly the various developments that have grown from the initial work of Slepian and Ludwig incident to the design and operation of the so-called ignitron tube, devoting principal attention to the problem of proper materials and design of the ignitor tip. This paper was published in full in the July issue.

The "Regulation of Grid-Controlled Rectifiers" was discussed at some length by L. A. Kilgore (A'29) and J. H. Cox (A'25) respectively design engineer and section engineer, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. They reported that "this paper discusses several factors which have not been included in the previously published regulation formulas and which should be considered in the practical application of rectifiers. Approximate solutions are given to take into account system reactance and the load inductance." Consideration also is given to the effect of grid pick-up characteristics on regulation, and means of modifying the inherent regulation characteristics by regulators or compensators. This paper was published in full in the September issue.

In discussing "The Igniter-Type Mercury Arc Rectifier as a Power-Conversion Unit," A. Lee Barrett, Pittsburgh Coal Company, Pittsburgh, Pa., reviewed briefly the changes since 1930 in coal-mining operations which have changed materially the problems of electric power supply. Strong tendencies toward mechanization, toward concentration of actual mining operations in smaller areas within a given mine, and toward multiple-shift operations have had at least 2 important effects upon requirements for electric supply: first, increasing the electric load at the working faces from the earlier total of about 25 per cent of the total mine load to the present figure of from 50 to 60 per cent of the total mine load; second, requiring more frequent relocation of underground substations. He reported some economic and mechanical details incident to recent and projected installations of underground rectifier substations of the igniter or multiple-tank type, stating that these "would seem to provide the mining industry with a substation no more expensive than contemporary substations. . . much more portable . . . efficiency is substantially better than anything heretofore available."

The use of "Mercury Arc Rectifiers in Chlorine Production" was described and explained by L. J. Rimlinger, chief electrical engineer, Columbia Chemical Company, Barberton, O. Mr. Rimlinger described a 7,000-kw 500-volt d-c rectifier installation recently placed in operation involving 2 2,000-kw 12-anode double-6-phase units each connected to an individual supply transformer, and one 3,000-kw unit involving 2 tanks operating on one transformer, 12 anodes each, and double-6-phase. To meet the requirements of electrochemical service he explained that "mercury arc rectifiers were selected for converting equipment because of their low operating cost, high efficiency, and their suitability in corrosive atmosphere."

### Lightning Versus Power Transmission

Lightning still is given a prominent position in discussions pertaining to electric power transmission. Three of the Akron papers dealt directly with this subject.

"Lightning-Proof Transmission Lines" of the Pennsylvania Water and Power Company were described by Edwin Hansson (A'19, M'35) and A. F. Bang (A'11) respectively transmission engineer and superintendent of operation for that company. The method of lightning protection described "consists of the proper combination of overhead ground wires, low tower-footing resistances obtained by means of a counterpoise, and ample insulation. Its successful application is illustrated by operating records . . . Performance of any given line can be predicted if the tower-footing resistances are known." Theory of protection outlines: "(1) that overhead ground wires must be placed so as to shield the conductors completely from direct strokes, thus eliminating flashovers from conductor to tower; (2) that the ground wires and towers must be so connected to earth that the current from the lightning stroke will be drained off without raising the potential of the structure to a value which will cause a flash from tower to conductor." Results cited: (1) 5 years operation of a 92-mile single-circuit 230-kv line with one lightning operation; (2) 3 years' operation of a 4-circuit 32-mile 132-kv line with no lightning operation; (3) $1\frac{1}{4}$ years' operation of a 2-circuit 23-mile 69-kv line with no lightning operation; "all lines located in severe lightning territory . . . average storms per year respectively, 62, 42, 39." This paper was closely related to a paper by S. K. Waldorf (A'27, M'36) test engineer of the same company, "Probable Outages of Shielded Transmission Lines," published in the May 1937 issue.

In discussing "Lightning Strokes in Field and Laboratory," P. L. Bellaschi (A'29, M'34) section engineer in charge of transformer engineering, Westinghouse Electric and Manufacturing Company, Sharon, Pa., concerned himself principally with the fundamental aspects of the problem, particularly with the characteristics of the lightning-stroke channel. He gave data and findings revealing further the nature of the channel core and of the resulting column, and submitted field observations for comparison purposes. This paper was published in full in the October issue.

"Cross-Catenary Transmission Lines for Lightning and Fog Conditions" were described by A. O. Austin (A'04, F'25) consulting and manufacturing engineer, Barberton, Ohio. Mr. Austin discussed 2 methods of achieving electrical reliability against lightning interruption: "In one method the ratio of the arcing voltage to the impedance in the lightning-diverting path constitutes the index of reliability where the line is equipped with ground wires. In the second case the high arcing voltage together with the limitation of current due to high ground resistance or other means produces a high resistance in the path to ground and prevents the follow-up of normal-frequency current." He further states that: "The ease of obtaining a high arcing voltage to ground with the cross-catenary type of construction makes it possible to develop either type to its maximum. The very high arcing voltage to ground with limited insulation between phases results in smaller structures and lower cost for a given standard. The double insulation in the cross-catenary construction provides a high degree of reliability not possible with single insulation. . . . The relative advantage is appreciable at lower voltages, but increases materially with the voltage. Clearance between phases or between conductors and ground which would be prohibitive with the usual types of construction can readily be obtained with the cross-catenary type. The development of low-capacitance high-voltage radio strain insulators removes the previous electrical and mechanical limitations of insulation for the cross span." Mr. Austin cited the "wide use of guyed cross-catenary construction for the Penn-

## Membership—

Mr. Institute Member:

The coming winter activities in national, District, and local groups will provide you with a strong appeal to your fellow workers when you speak to them about AIEE membership. An invitation to participate with you in these meetings and other affairs, when permissible, should prove helpful in creating a better understanding of Institute aims and activities. If one or more of your associates should indicate an interest in joining, and if you feel he or they would make desirable members, please let your membership committeeman know about it.

C. M. Foust

Vice-Chairman, District No. 1
National Membership Committee

sylvania Railroad for its recent electrification" as showing "a growing trend toward the use of the cross-catenary construction."

### D-C Transmission

"Possibilities of Direct-Current Power Transmission Using Electrically Controlled Rectifiers and Inverters," were discussed by O. K. Marti (A'21, M'27), engineer in charge of rectifiers and railway equipment, Allis-Chalmers Manufacturing Company, Milwaukee, Wis. He outlined some of the problems of power system stability; he stated that "from preliminary considerations it would appear that these difficulties in transmitting power would be overcome if direct current were used, and it therefore seems justifiable to look carefully into the possibility of transmitting power by means of direct current. This is particularly true since it appears to be possible by means of the latest development of the grid-controlled electric power valve to convert a-c power to d-c at high-voltage, for d-c transmission, and invert the d-c power back into a-c of any desired frequency and voltage, without great cost and with little loss of power." He reported briefly the high lights of 30 years of operating experience with the 275-mile 125-kv d-c transmission system between Mougiers and Lyon, France, in connection with which were put into practical application the original development of Rene Thury, the Swiss consulting engineer, who is generally regarded as the father of d-c high-voltage transmission.

Mr. Marti stated that "it seems now that the argument between the proponents of direct and alternating currents will again be revived. The principal reason for this is the fact that the electronic power valve has reached a stage of development where it can be employed without difficulty to handle the high voltages and currents coming into consideration for the commercial transmission of electric power."

### Student Program

More than 130 electrical-engineering students—nearly a third of all those attending the Akron meeting—contributed to the effectiveness of the general program and themselves held a technical session that drew not only full attendance from their own group, but also a good many practicing engineers from the general session that was held in parallel. General arrangements for the students' participation in the program were under the direction of J. T. Walther (A'19, M'26) professor of electrical engineering, and counselor of the Student Branch at the University of Akron, and past-chairman (1924–25) of the Akron Section.

The 6 papers presented on the student technical session program were as follows:

Measurement of Reverberation Time with the Cathode-Ray Oscillograph, H. W. Lensner, Case School of Applied Science.

We, The Students, Nelson A. Powell, Ohio University.

Pressure Insulated Conductor for High-Voltage Transmission, J. B. Adams, Jr., Johns Hopkins University.

The Telephone Inverter, Frank Andrix, Ohio State University.

An Engineer's Training, A. H. Graham, West Virginia University.

Saturable Core Reactor, Robert F. Miller, University of Akron.

Subsequent to the technical session, the chairmen and the student counselors of the various Student Branches in the Middle Eastern District gathered in separate groups for conferences and an exchange of ideas concerning the effective conduct of Student Branch activities. Following these conference group meetings, a general luncheon of the 2 groups was held, supplemented by others interested in student affairs including President W. H. Harrison, National Secretary H. H. Henline, Past-President A. M. MacCutcheon, Past-Chairman O. W. Eshbach of the AIEE committee on education, and Editor G. R. Henninger. Actions reported at this meeting included:

1. Decision to hold 1938 student conference at Bucknell University, Lewisburg, Pa.; date to be announced later.

2. Selection of Doctor A. C. Seletzky, faculty counselor of the Student Branch at Case School of Applied Science, Cleveland, as chairman of the District committee on student activities, for the year beginning August 1, 1938.

3. Selection of Professor J. T. Walther to serve as the District student-counselor representative at the 1938 summer convention in Washington, D. C.

Asked for a "few remarks," President Harrison spoke briefly but forcefully and effectively on the subject "Minding Our Own Business." The theme of his brief address was to the effect that the important engineering requirements of the modern world can be met best by seasoned engineers having a broad background of experience. He urged engineering students to give primary attention to the acquisition of a sound and fundamental technical training, rather than to be led too far afield into other subjects during student days.

### Inspection Trips and Entertainment

The variety of important industrial activities to be found in the vicinity of Akron afforded excellent opportunities for interesting and instructive inspection trips.

The principal event was the all-afternoon-and-evening trip to Nela Park, Cleveland, where some 300 of those attending the meeting were the guests of the General Electric Company. The program included escorted tours through the laboratories devoted to the experimental development and manufacture of electric lamps of various sizes, demonstration lectures on commercial and industrial illumination for the men and on home economics and illumination for the women, a generous dinner, and as a finale a demonstration lecture in the auditorium of the General Electric Institute covering briefly the evolution of illumination and some of the major contributions made by scientific research.

Another general event, heavily-attended was an evening trip to the Daniel Guggenheim Airship Institute where men and women alike enjoyed the inspection and demonstration of the vertical wind tunnel and its 110-mile-per-hour blast, various equipment for the pursuit of aeronautical research, and small-scale test models of dirigible aircraft. Although originally founded for research in the field of lighter-than-air craft, the Guggenheim Institute is now using available time and facilities for research in other suitable fields, such as mine ventilation as reported by Director Troller at one of the technical sessions.

A large group interested in power-plant equipment took advantage of the opportunity to visit the Barberton plant of the Babcock and Wilcox Company where the various fabrication processes incident to the manufacture of boilers, pulverized-coal equipment, and other power-plant equipment were witnessed in full swing under shop conditions. Of particular interest were the large and extremely heavy boiler drums being manufactured for new power plants where new levels of high pressures and temperatures are being pioneered.

A large crowd likewise attended the all-afternoon trip through the Barberton plant of the Ohio Brass Company, where the many steps in the manufacture of porcelain insulators of various types were followed through from their beginnings in raw material to their finishing, high-voltage testing, and packing into crates for shipment. The afternoon's program was topped off by a demonstration of the high-voltage labora-

tory equipment, featuring both commercial testing and some of the more spectacular high-voltage phenomena.

Automobile tire manufacture was followed through from crude rubber to finished product by a group that enjoyed the hospitality of the B. F. Goodrich Company. Various other special trips were arranged for other groups.

The women in attendance were generously provided for in the special features of the entertainment program. In fact, they were kept quite busy with a program starting with a guest luncheon Wednesday noon and providing a continuous series of activities that ended only with the concluding general banquet, Friday evening. The progam included an afternoon garden pilgrimage through the estates of F. A. Seiberling and L. A. Laurson, games and luncheon at the Portage Country Club, inspection of the Akron Air Dock and guest excursion on one of the Goodyear blimps, and a bridge-tea at the home of Mrs. A. O. Austin in Barberton.

### Commander Rosendahl Defends Dirigibles

Commander C. E. Rosendahl of the United States Navy, widely renowned for his pioneering efforts and leadership in the field of air navigation, spoke at the banquet on the subject "Lighter-Than-Air Craft." Commander Rosendahl carried all in the crowded banquet room along with him as he described and explained some of the more important features of lighter-than-air craft, and outlined his opinion of their inevitable and vitally important place in the field of modern transportation. He drew a convincing word picture of such craft in what he strongly termed "proper place"—as an important adjunct to other modes of transportation in the air and on the land and sea, and in both commercial and naval use.

In commercial transportation, Commander Rosendahl pictured the dirigible airship as a logical mode of long-distance high-speed travel, particularly on transoceanic routes where their "pay load" capacity and their long-range cruising ability he considers as already well-demonstrated by the world tour of the "Graf Zeppelin" and the long service of such craft in trans-Atlantic commercial service between Germany and South American ports. He emphatically assigned the "Hindenburg" disaster to the inflammability of hydrogen rather than to any defect in craft or handling. He stated that by its ability to maintain a continuous day and night air speed of about 85 miles an hour the modern dirigible aircraft could cross the Pacific in 4 days whereas the heavier-than-air craft now in that service require 6 days because of the necessity for intermittent flying and in spite of their higher speed when in the air.

For naval service, Commander Rosendahl considers the dirigible airship to be a vital part of the intelligence and scouting service, leaving the fighting to be done by planes and surface crafts better fitted for that service. The commander's talk was thoroughly understandable and well received.

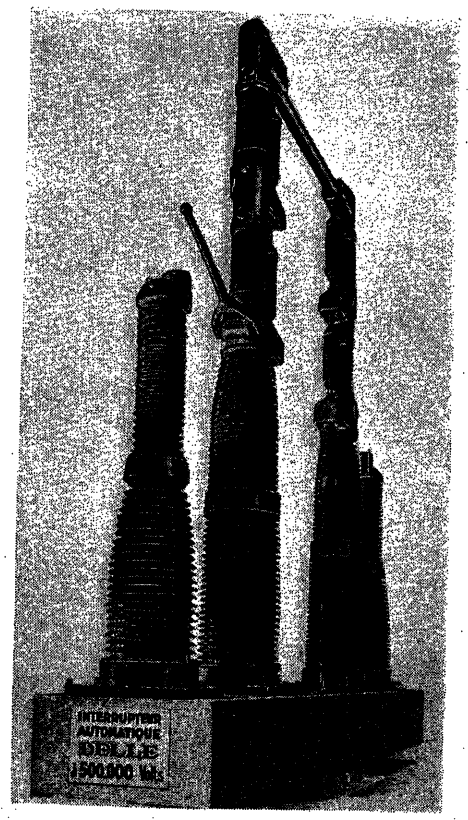
### District Executive Committee Meeting

The Middle Eastern District executive committee met in Akron, Saturday morning, October 16, following the District meeting, for a busy session involving a wide range of matters incident to District affairs and activities. Attendance at the meeting was recorded as follows:

I. Melville Stein, vice-president AIEE, presiding
H. A. Dambly, District secretary
M. W. Smith, District vice-chairman, membership committee
L. S. Billau, chairman, Baltimore Section
J. A. Noertker, chairman, Cincinnati Section
F. E. Harrell, chairman, Cleveland Section
W. L. Everitt, secretary, Columbus Section
W. D. Bearce, secretary, Erie Section
E. F. De Turk, chairman, Lehigh Valley Section
J. B. Harris, Jr., chairman, Philadelphia Section
W. A. Furst, secretary, Pittsburgh Section
H. S. Smith, chairman, Sharon Section
H. R. Daykin, secretary, Toledo Section
A. G. Ennis, representing Washington Section

## Wichita Section Holds First Meetings

The organization meeting of the AIEE Wichita Section, authorized by the Institute's board of directors on June 24, 1937, was held September 16, 1937, at Wichita, Kans., with an attendance of 17. By-laws were adopted, and R. R. Miner (A'30) electrical engineer for the Kansas Gas and Electric Company, and W. A. Wolfe (A'30, M'36) relay engineer for the same company, were elected chairman and secretary-treasurer, respectively, to serve until August 1, 1938. Other members of the executive committee are E. E. Powell (A'37), G. LeRoy Quigley (A'32), and J. A. Rupf (A'33).



On September 30 a dinner meeting was held with 34 members and guests present. Doctor W. M. Jardine, president of the University of Wichita and former Secretary of Agriculture, was toastmaster, and speakers included L. T. Blaisdell (A'20, M'22) AIEE vice-president, whose subject was "The AIEE and the Electrical Engineering Profession."

Section committee chairmen are H. E. Margrave (A'37) membership; P. S. Colby (A'37) meetings and papers, and R. B. Gow (A'35) arrangements.

**Former Edison Secretary Dead.** At the age of 84, W. H. Meadowcroft, former secretary to Thomas A. Edison, died October 15, 1937, at his home in Boonton, N. J. Mr. Meadowcroft was born in Manchester, England, May 29, 1853, where he received his common and high school education. He came to the United States in 1875, and for the succeeding 6 years he was employed by the law firm of Carter and Eaton in New York City, being admitted to the New York bar in 1881. In that year he became affiliated with the Thomas A. Edison enterprises, and from 1910 until Edison's death in 1931 he was assistant and confidential secretary to Mr. Edison. Mr. Meadowcroft was founder and historian of the Edison Pioneers, of which organization he served as president in 1927. He was honorary vice-president of the Thomas Alva Edison Foundation, Inc., which was established in 1935 for the purpose of creating a living tribute to the inventor. He was the author of several books.

**Training of Skilled Workers.** A recent survey by the National Industrial Conference Board indicates that 4 out of every 5 companies have adopted some form of training for industrial work in order to meet present and future needs for skilled workers. The results of the board's survey, which included 473 companies in various industries and in different sections of the United States, are presented in a report, "Training for Industry." This report shows that training on the job is the method generally used, only 8.5 per cent of the companies surveyed maintaining so-called vestibule schools. Systematic apprentice training is reported by 272 companies, the time required ranging from one week to more than 5 years. Compensation is shown to be at least 50 per cent of the regular rate in over 90 per cent of the companies surveyed, and 80 per cent of the regular rate in about 32 per cent of the companies. Training is given to mature persons and regular employees as well as to youths and beginners, but in most companies not to persons under 18. Women as well as men are offered training opportunities in some companies.

## Large Circuit Breaker Exhibited at Paris Fair

CONSTRUCTED by Ateliers de Constructions Electriques de Delle, Villeurbanne, France, the circuit breaker and disconnecting switch shown here is being exhibited in the Palace of Light of the International Exposition of Paris. This unit, said to be the largest in the world, is designed for operation at 500 kv at 500 amperes and has an interrupting capacity of 5,000,000 kva.

# Nomination of AIEE Officers for 1938 Election; Members' Suggestions Invited Until December 15

FOR the nomination of national officers to be voted upon in the spring of 1938, the AIEE national nominating committee will meet during the winter convention, January 24–28, 1938. To guide this committee in performing its constituted task, suggestions from the membership are, of course, highly desirable. To be available for the consideration of the committee, all such suggestions must be received by the secretary of the committee at Institute headquarters, not later than December 15, 1937.

In accordance with the provisions in the constitution and by-laws, as amended during 1935 and quoted in the following paragraphs, actions relative to the organization of the national nominating committee are now under way.

**Constitution**

28. There shall be constituted each year a national nominating committee consisting of one representative of each geographical district, elected by its executive committee, and other members chosen by and from the board of directors not exceeding in number the number of geographical districts; all to be selected when and as provided in the by-laws. The national secretary of the Institute shall be the secretary of the national nominating committee, without voting power.

29. The executive committee of each geographical district shall act as a nominating committee of the candidate for election as vice-president of that district, or for filling a vacancy in such office for an unexpired term, whenever a vacancy occurs.

30. The national nominating committee shall receive such suggestions and proposals as any member or group of members may desire to offer, such suggestions being sent to the secretary of the committee.

The national nominating committee shall name on or before January 31 of each year, one or more candidates for president, national treasurer, and the proper number of directors, and shall include in its ticket such candidates for vice-presidents as have been named by the nominating committees of the respective geographical districts, if received by the national nominating committee when and as provided in the by-laws; otherwise the national nominating committee shall nominate one or more candidates for vice-president(s) from the district(s) concerned.

**By-Laws**

SEC. 22. During September of each year, the secretary of the national nominating committee shall notify the chairman of the executive committee of each geographical district that by December 15 of that year the executive committee of each district must select a member of that district to serve as a member of the national nominating committee and shall, by December 15, notify the secretary of the national nominating committee of the name of the member selected.

During September of each year, the secretary of the national nominating committee shall notify the chairman of the executive committee of each geographical district in which there is or will be during the year a vacancy in the office of vice-president, that by December 15 of that year a nomination for a vice-president from that district, made by the district executive committee, must be in the hands of the secretary of the national nominating committee.

Between October 1 and December 15 of each year, the board of directors shall choose 5 of its members to serve on the national nominating committee and shall notify the secretary of that committee of the names so selected, and shall also notify the 5 members selected.

The secretary of the national nominating committee shall give the 15 members so selected not less than 10 days' notice of the first meeting of the committee, which shall be held not later than January 31. At this meeting, the committee shall elect a chairman and shall proceed to make up a ticket of nominees for the offices to be filled at the next election. All suggestions to be considered by the national nominating committee must be received by the secretary of the committee by December 15. The nominations as made by the national nominating committee shall be published in the March issue of ELECTRICAL ENGINEERING (Journal of AIEE), or otherwise mailed to the Institute membership not later than the first week in March.

INDEPENDENT NOMINATIONS

Independent nominations may be made in accordance with provisions in Section 31 of the constitution and Section 23 of the by-laws, which are quoted below:

**Constitution**

31. Independent nominations may be made by a petition of twenty-five (25) or more members sent to the national secretary when and as provided in the by-laws; such petitions for the nomination of vice-presidents shall be signed only by members within the district concerned.

**By-Laws**

SEC. 23. Petitions proposing the names of candidates as independent nominations for the various offices to be filled at the ensuing election, in accordance with Article VI, Section 31 ( constitution), must be received by the secretary of the national nominating committee not later than March 25th of each year, to be placed before that committee for the inclusion in the ballot of such candidates as are eligible.

On the ballot prepared by the national nominating committee in accordance with Article VI of the constitution and sent by the national secretary to all qualified voters during the first week in April of each year, the names of the candidates shall be grouped alphabetically under the name of the office for which each is a candidate.

(*Signed*) H. H. HENLINE,
November 1, 1937 *National Secretary*

# Lehigh Valley Section Sponsors Joint Meeting

An engineers' dinner meeting, attended by more than 400 persons, was held at the Jermyn Hotel, Scranton, Pa., October 9, 1937, under joint sponsorship of the AIEE Lehigh Valley Section, the local sections of the American Institute of Mining and Metallurgical Engineers, and The American Society of Mechanical Engineers, and the chambers of commerce of Scranton, Wilkes-Barre, Hazleton, and Pottsville. A report of the meeting was made available by W. H. Lesser (M'24) of J. H. Pierce and Company, Scranton, a past-chairman of the Lehigh Valley Section, who was chairman of the committee on arrangements and who also acted as toastmaster and presiding officer at the meeting.

Following the dinner those attending heard 3 addresses; 2 speakers dealt with the anthracite coal industry, one of the chief industries of the Lehigh Valley Section, and the other was concerned with one phase of the electrical industry. In the first talk of the evening Philip Sporn (A'20, F'30) vice-president and chief engineer of the American Gas and Electric Company, New York, N. Y., outlined broadly, yet using some specific examples to illustrate his assertions, the operation of electric power systems on an interconnected and co-ordinated basis. He stated that "the development of the electric utility systems of the United States on an interconnected and co-ordinated basis has resulted in giving the United States a preeminent position in the field of electric power supply." In the next address, Cadwallader Evans, Jr., vice-president and general manager of the Hudson Coal Company, Scranton, spoke on "Looking Ahead in Anthracite," outlining some of the operating problems in the coal-mining industry and sketched its future as it appears today. The latest efforts of the anthracite industry to promote the sale of its product were described by the third speaker, Frank W. Earnest, Jr., president of Anthracite Industries, Inc., New York, N. Y. He emphasized the improved competitive position of the anthracite industry, and painted a bright picture of the future of that business. This was the second of 2 such jointly sponsored meetings, the first having been held in October 1935 at Wilkes-Barre, Pa.

# Winter Convention to Include General Session

Because the "general session" held during the Institute's 1937 summer convention at Milwaukee, Wis., evoked so much interest, a somewhat similar session is being arranged for the forthcoming 1938 AIEE winter convention to be held in New York, N. Y., January 24–28. According to present plans, a speaker of national repute will address the session on a subject of broad interest to the engineering profession, and to electrical engineers in particular. A special committee to make the necessary arrangements for the session has been appointed consisting of the following: H. S. Bennion, C. R. Beardsley, L. W. W. Morrow, H. S. Osborne, and W. E. Wickenden.

Although the technical program is still in the formative stage, sessions on the following subjects are tentatively scheduled: electronics, communication, electrical machinery, power transmission and distribution, protective devices, transportation, instruments and measurements, education, electric welding, research, and basic sciences. In addition, several technical conferences are expected to be held; 3 such conferences already have been tentatively scheduled, one on active networks under sponsorship of the committee on communication, and 2 under sponsorship of the committee on basic sciences.

Details concerning these and other features of the convention program will be included in a later issue of ELECTRICAL ENGINEERING.

**New ASTM Standards.** At a recent meeting of committee *E*-10 on standards of the American Society for Testing Materials, 11 new tentative standards were recommended. Among these were the following, covering specifications and test methods for electrical materials:

1. SPECIFICATIONS FOR PHENOLIC LAMINATED SHEET FOR RADIO APPLICATIONS (*D* 467–37 *T*).
2. METHOD OF TESTING PIN-TYPE SODA-LIME GLASS INSULATORS (*D* 468–37 *T*).
3. METHODS OF TEST FOR RUBBER INSULATED WIRE AND CABLE (*D* 470–37 *T*).

# Fifth Annual Meeting of ECPD Held; Accrediting of Engineering Curricula Extended

THE fifth annual meeting of Engineers' Council for Professional Development was held October 1, 1937, in the Engineerng Societies Building, New York, N. Y. Election of officers, appointment of committees, and presentation of the annual reports of Council's committees constituted the principal items of business. Council approved the accrediting of additional curricula in engineering schools, as recommended by the committee on engineering schools, making a total of 442 curricula now accredited in 127 institutions (see tabulation elsewhere in this report).

Excerpts from the complete reports of the committees on student selection and guidance, professional training, and engineering schools follow the item on election of officers and appointment of committees; the report of the committee on professional recognition was held over as an order of business for a later meeting of ECPD executive council, and was referred back to the committee for further consideration.

Chairman Chas. F. Scott (A'92, F'25, HM'29, past-president) in opening the meeting presented a prepared review of ECPD's activities to date, calling attention to its principal objectives and outlining various possibilities for increased effectiveness of ECPD's efforts as a joint agency for the engineering societies. "Supplementing 'general objectives' in our charter," said Doctor Scott, "is an 'immediate objective'—the development of the young engineer for some 10 years from high school to professional recognition. It is in several stages. In the pre-freshman stage ECPD is to present 'the responsibilities and opportunities of engineers'; in engineering schools it is to 'formulate... a sound educational foundation for the practice of engineering'; and after graduation it is to 'further personal and professional development of young engineering graduates.' "

## Elections and Appointments Reported

Chas. F. Scott, professor of electrical engineering emeritus, Yale University, was re-elected ECPD chairman. A. B. Parsons, secretary of the American Institute of Mining and Metallurgical Engineers, was elected secretary, and C. E. Davies, secretary of the American Society of Mechanical Engineers, was re-elected assistant secretary of Council. Chairmen of 3 ECPD committees were re-elected as follows: student selection and guidance, R. L. Sackett, dean emeritus of college of engineering, Pennsylvania State College; engineering schools, Karl T. Compton (F'31), president, Massachusetts Institute of Technology; and professional recognition, C. N. Lauer, president, Philadelphia (Pa.) Gas Works. O. W. Eshbach (A'17, F'37) American Telephone and Telegraph Company, New York, N. Y., was appointed chairman of the committee on professional training; he has served as acting chairman since the death of General R. I. Rees, former chairman of the committee.

Executive committee members reappointed were: J. P. H. Perry, representing the American Society of Civil Engineers; C. F. Hirshfeld (A'05, F'36) representing the American Society of Mechanical Engineers; L. W. W. Morrow (A'13, F'25, director) representing the AIEE; H. C. Parmelee, representing the American Institute of Chemical Engineers; and D. B. Steinman, representing the National Council of State Boards of Engineering Examiners. Members newly appointed to the executive committee were: D. C. Jackson (A'87, F'12, past president) representing the Society for the Promotion of Engineering Education [alternate R. E. Doherty (A'16, M'27)]; and W. B. Heroy, representing the American Institute of Mining and Metallurgical Engineers.

Appointments of representatives of the participating societies for the 3-year term 1937–40 were announced as follows: ASCE, J. P. H. Perry (reappointment); ASME, A. R. Stevenson, Jr. (reappointment); AIME, W. B. Heroy; AIChE, B. F. Dodge; SPEE, R. E. Doherty; AIEE, F. Ellis Johnson; NCSBEE, J. S. Dodds.

## Report of Committee on Professional Training

O. W. Eshbach, Acting Chairman

The untimely death, during the past year, of the chairman, General R. I. Rees, seriously affected progress toward the objectives expressed in previous reports. His full time activity being essential to the realization of the year's program, it became necessary to adjust the work of the committee to more restricted projects.

The program recommended in the 1936 report may be simply expressed in terms of 3 general objectives.

1. To prepare and distribute information which would stimulate and assist junior engineers in self-development.

2. To give assistance in local organization of juniors so as to provide means of achieving their objectives.

3. To study the desires and needs of younger engineers as their activities develop and ideas crystallize, so that additional efforts can be made most effective.

While substantial progress has been made in the first 2 objectives, not much has been achieved in obtaining a better understanding of future needs. By nature, this is a continuing problem, varying in time and locality. It requires an accumulation of experience and the constant attention of the committee as local activities develop.

*Local Organizations and Activities.* At the 1936 annual meeting, the committee considered as its second major undertaking for 1936–37 the stimulation of programs similar to that at Providence in an increasingly large number of centers, having local sections of the constituent bodies and junior engineers form the basis of operations. The success of the Providence trial organization, which has continued its activities during the past year and reports of their experience given wide circulation, prompted General Rees to plan a trip in October and November, 1936, to Cleveland, Chicago, St. Louis, Detroit, and Pittsburgh to discuss the development of junior programs in these areas. Plans were interrupted by his sudden death in Detroit, on November 23. Through the voluntary assistance of Doctor C. F. Hirshfeld, joint meetings with representatives of local engineering societies and the national societies were held in both Detroit and Chicago, completing the itinerary. As a result of these visits, active organization work has been undertaken and plans are in progress for this fall to initiate further progress in junior activities. In addition to the activities started by General Rees, junior committees have been formed in Hartford and Boston and are being considered by the Worcester Engineering Society.

During the spring and summer the committee has been studying the trend of junior organization developments. From reports of the participating societies and other sources, it was found that some form of junior organization, sponsored either jointly or separately by local sections of the national societies, was in existence or being formed in 39 localities.

While recent in origin most of these organizations have come about through the normal activities of the sections of national societies. In most cases they are sponsored by a single society but include in their membership juniors of other affiliations. The spontaneity of these developments is encouraging. They present opportunities for co-operation which should be considered jointly by the sections in the several localities.

*Principles of Organization of Local Activities.* The principal objective of local organization has been to afford opportunity for personal development in accord with the ideals set forth by the ECPD. The general and sequential procedure in starting junior activities has been as indicated in many letters and reports as follows:

1. The selection of experienced engineers of the community who have expressed interest and willingness to act as advisors and a group of junior engineers representative of different professional interests.

2. Effecting an organization of juniors which gives opportunity for them to frame their own ideas as to the form it takes.

3. Encouraging the development of a serious and effective program of activity consistent with the wishes of the group and the ideals of the purpose.

While this general statement typifies the procedures followed, the initiation by the advisors or originators may come in 3 different ways.

1. Local engineering clubs may sponsor the junior organization through representatives of their professional divisions and thus effect co-ordination with the section activities of the national engineering societies.

2. Representatives of the several sections of the national societies may undertake to start and co-ordinate junior activities by forming a special joint activity or junior advisory committee.

3. The sections of national societies may act independently and not concurrently.

The first 2 ways have the advantage of co-ordination in programs of social and pro-

fessionally common interests. The last has the advantage of flexibility and speed in getting underway but the disadvantage of lack of co-ordination in matters of common interest and united effort toward the stimulation of professional unity.

In whatever manner these organizations originate it seems desirable that they should be the accomplishment of local sections of the constituent bodies of ECPD and that the committee on professional training should aim to give the constituent bodies such assistance as necessity requires and is reasonable to provide. In this connection there is at present no common committee organization within local sections, and no common classification of membership which together with reasonably uniform section areas would greatly enhance the opportunity for local and national co-operation.

*Junior Committee Recommendations.* The annual report of the junior committee in 1936 stresses as important problems:

1. Stimulation of junior interest in the entire ECPD program.
2. Organization of groups in local areas.
3. Development of training material.
4. Development of means of qualifying for professional recognition.

During the year progress has been made by ECPD in the first 2 problems. During the coming year the committee on professional training plans to study the junior programs now in progress and give attention to such needs as are in evidence.

*Publications and Their Distribution.* Since the organization of ECPD the committee on professional training has prepared and published the following pamphlets, among others:

"Suggestions to Junior Engineers." A personal appraisal blank to assist in planning a definite program of development; supplemented by a nontechnical reading list, classified under 10 general subjects.

"Selected Bibliography of Engineering Subjects." A selection of widely recommended texts, mostly of college grade, prepared with the co-operation of over 100 practicing engineers and teachers in 1937:

I. Mathematics, mechanics, and physics
II. Aeronautical and civil engineering
III. Chemical and industrial engineering
IV. Electrical and mechanical engineering
V. Metallurgical and mining engineering

"University Extension Facilities." A list of 24 institutions with description of nontechnical courses given by class study or by correspondence. Prepared by the junior committee in 1935.

During the past year considerable effort was spent in the final editing of the "Selected Bibliography of Engineering Subjects" and its distribution. Copies were sent to all who co-operated in its preparation, the deans of engineering schools, selected publishers of trade magazines, and librarians. The listing of all ECPD publications in the sections of the bibliography was called to the attention of the recipients with the purpose of affording teachers and others the opportunity of directing the attention of students to the interest of the profession in their development, and expediting individual efforts in organizing programs of self-development after graduation. Thus there have been made available at nominal fees an aid for self-analysis, references for both cultural and technical study, and suggestions of study facilities through university extension. To further publicize the program of Council and emphasize the need for continued development, the committee has prepared a small folder, appendix *C*1, and recommends a wide distribution of it to fill the need which has been felt for a short account of the organization, purpose, plans and accomplishment of ECPD. The reprinting of selected articles, both by ECPD and in engineering magazines, is also recommended to aid in reports of progress and better understanding of aims and activities. In this connection 2 articles were reprinted by the committee and several appeared in national societies' publications. A particularly well-prepared article on "The Providence Experiment in Junior Engineers' Development" was reprinted from *Chemical and Metallurgical Engineering*, volume 44, March 1937, and distributed through the national societies to the sections of their societies. It is hoped that as progress in other localities is reported the details of their experiences may be publicized in similar manner.

## Report of Committee on Student Selection and Guidance

R. L. Sackett, Chairman

*English and Mathematics Tests.* The study of the academic history of entering engineering students who were given the co-operative tests in English and mathematics in 1933 and 1934 has been continued. Results noted in previous reports are confirmed by the evidence from the 12 institutions giving the tests. Of those students who discontinued, the larger proportion dropped out voluntarily because of dissatisfaction with themselves, lack of finances, or other conditions. It is safe to say that some had little or no effective guidance and if they had received good counsel, would not have undertaken an engineering education. Scholarship, sound objectives, the will to win, or other qualifications were lacking. The English and mathematics tests indicated that these individuals were invariably low grade for educational refinement. That the lack of the scholarship which is required for reasonable success in engineering education can be detected by such tests, or others, or by examination of the high-school record, is beyond dispute.

*Engineering: A Career—A Culture.* The more general use of the pamphlet of this title is a source of satisfaction. The subcommittee has revised the material and is prepared to submit a copy for a new and improved edition as soon as the present one is exhausted.

*Guidance Manual.* The "Manual on Guidance," prepared by the committee, is being used increasingly and is helpful to the committees of engineers, to colleges, and to high schools. It has been mimeographed and distributed, without charge, to those vitally interested.

*High-School Guidance.* A notable increase in interest in the subject of guidance for high-school students has been observed. Articles in magazines and in the daily press are evidence of the growing appreciation of the economic and social importance of sound vocational counsel.

*Selection by the College.* To cull some 20,000 prospective engineering freshmen from hundreds of thousands of seniors, in thousands of high schools, for entrance to 150 engineering schools, is a mighty task. Upon it, however, depend the careers of individuals, the efficacy of engineering schools, the quality of the engineering profession, and its contribution to the interest of the general public. The usefulness of the engineer depends on personality as well as technical proficiency.

The increase in college enrollments has brought financial and social problems of grave importance.* Limiting enrollments has been suggested but no generally accepted basis for restriction has yet been found. Various methods have been used, such as college board examinations and batteries of training and aptitude tests. There is no doubt that limiting enrollment in engineering to those of high scholastic standing, judged by the 4-year high- or preparatory-school record, is distinctly helpful.

In order to assist in better precollege guidance, engineering schools have been urged to use their influence and faculties in promoting better guidance in the high schools within their spheres of influence.

*Guidance by Engineering Societies.* The national engineering societies have been urged to organize local committees of interested engineers who approach the public-school authorities and offer their services as counselors to students who are interested in engineering. The purpose is to bring the student into closer contact with the realities of engineering education and the practical work which the engineer does—especially the young engineer. Among the cities which have made a notable success of such joint efforts are Detroit, Denver, Milwaukee, Kansas City, Rochester, and St. Louis.

*Selective Tests.* Search, experiment, and evaluation of tests suitable for extracting aptitudes of importance in the prospective engineering student are being conducted by various psychologists and committees. The validity has not yet been established or the committee has not yet had data submitted to it to establish the value of new tests or small groups of tests. That tests of value have been or will be established is beyond doubt. That they may be of great assistance in guidance and selection is equally certain. But discretion in their use and judgment are also necessary in their application. A large measure of responsibility will still rest on those using tests to evaluate personal qualities which tests cannot be expected to expose, at least in the present state of the art.

*Guidance in Public Schools.* City schools are organizing public programs followed by personal counsel for those desirous of entering one of the professions. The majority of the better high schools have counselors and are developing guidance for those thinking of engineering or other vocations. In some of them there is a definite need for an experienced approach to the subject. This, the practicing engineer can supply if he has the interest and an understanding of what youth needs in the way of information about the demands made on the novitiate and the later rewards. More emphasis should be placed on interests, aptitudes, ambitions, and personal qualities and less on "how much does it pay?"

* W. M. Kotschnig, *The Educational Record*, July 1937.

# List of Undergraduate Curricula of Educational Institutions Accredited by ECPD

(As of October 1, 1937, and subject to continual revision)

**University of Alabama:** Aeronautical, civil, electrical, industrial, mechanical, mining

**University of Arizona:** Civil, electrical, mechanical, mining

**University of Arkansas:** Civil, electrical, mechanical

**Armour Institute of Technology:** Chemical, civil, electrical, mechanical

**Brown University:** Civil, electrical, mechanical

**Bucknell University:** Civil, electrical

**University of California:** Civil, electrical, mechanical, metallurgical (metallurgy), mining, petroleum

**California Institute of Technology:** Aeronautical (6-year course), chemical (5-year course), civil, electrical, mechanical

**Carnegie Institute of Technology:** Chemical, civil (*a*), electrical (*a*), industrial (management) (*a*), mechanical (*a*), metallurgical (*a*)

**Case School of Applied Science:** Chemical, civil, electrical, mechanical, metallurgical

**University of Cincinnati:** Aeronautical, chemical, civil, electrical, mechanical

**The Citadel:** Civil

**Clarkson College of Technology:** Civil, electrical, mechanical

**Clemson Agricultural College:** Civil, electrical, mechanical

**College of the City of New York** (*a*): Civil, electrical, mechanical

**University of Colorado:** Architectural, civil, electrical, mechanical

**Colorado School of Mines:** Geological, metallurgical, mining, petroleum

**Columbia University** (*b*): Chemical, civil, electrical, industrial, mechanical, metallurgical, mining

**Cooper Union Institute of Technology** (*c*): Civil, electrical, mechanical

**Cornell University:** Chemical, civil, electrical, industrial (administrative), mechanical

**Dartmouth College:** Civil

**University of Delaware:** Civil, electrical, mechanical

**University of Detroit:** Aeronautical, architectural, civil, electrical, mechanical

**Drexel Institute:** Chemical, civil, electrical, mechanical

**Duke University:** Civil, electrical, mechanical

**University of Florida:** Civil, electrical, industrial, mechanical

**Georgia School of Technology:** Aeronautical, civil (*d*), electrical (*d*), mechanical (*d*)

**Harvard University** (*e*): Civil, communication, electrical, industrial (engineering and business administration), mechanical, metallurgical (physical metallurgy), sanitary

**Howard University:** Civil, electrical, mechanical

**University of Idaho:** Civil, electrical, mechanical

**University of Illinois:** Architectural, ceramic (technical option), chemical, civil, electrical, general (*f*), mechanical, metallurgical, mining

**Iowa State College:** Agricultural (*g*), architectural, chemical, civil, electrical, general (*f*), mechanical

**State University of Iowa:** Chemical, civil, electrical, mechanical

**Johns Hopkins University:** Civil, electrical, mechanical

**University of Kansas:** Architectural, civil, electrical, mechanical, mining

**Kansas State College:** Agricultural (*g*), architectural, civil, electrical, mechanical

**University of Kentucky:** Civil, metallurgical, mining

**Lafayette College:** Civil, electrical, industrial (administrative), mechanical, metallurgical, mining

**Lehigh University:** Chemical, civil, electrical, industrial, mechanical, metallurgical, mining

**Louisiana State University:** Civil, electrical, mechanical, petroleum

**University of Louisville:** Chemical, civil, electrical, mechanical

**University of Maine:** Civil, electrical, general (*f*), mechanical

**Marquette University:** Civil, electrical, mechanical

**University of Maryland:** Civil, electrical, mechanical

**Massachusetts Institute of Technology:** Aeronautical, architectural, building engineering and construction, chemical, civil, electrical, electrochemical, general (*f*), industrial (business and engineering administration), mechanical, metallurgical (metallurgy), mining, naval architecture and marine engineering, public health, sanitary

**University of Michigan:** Aeronautical, chemical, civil, electrical, engineering mechanics, mechanical, metallurgical, naval architecture and marine engineering, transportation

**Michigan College of Mining and Technology:** Civil, electrical, mechanical, metallurgical, mining

**Michigan State College:** Civil, electrical, mechanical

**University of Minnesota:** Aeronautical, chemical, civil, electrical, mechanical, metallurgical, mining (excluding mining in geology option), petroleum

**University of Missouri:** Civil, electrical, mechanical

**Missouri School of Mines and Metallurgy:** Ceramic, civil, electrical, metallurgical, mining (mine) (excluding mining geology option)

**Montana School of Mines:** Geological, metallurgical, mining

**Montana State College:** Civil, electrical, mechanical

**University of Nebraska:** Agricultural (*g*), architectural, civil, electrical, mechanical

**University of Nevada:** Electrical, mining

**University of New Hampshire:** Civil, electrical, mechanical

**University of New Mexico:** Civil, electrical, mechanical

**New York University:** Aeronautical, chemical (*h*), civil (*a*), electrical (*a*), mechanical (*a*)

**New York State College of Ceramics** (at Alfred University): Ceramic

**Newark College of Engineering:** Civil, electrical, mechanical

**North Carolina State College:** Ceramic, civil, electrical, mechanical

**University of North Dakota:** Civil, electrical, mechanical, mining

**Norwich University:** Civil, electrical

**Ohio State University:** Ceramic, chemical, civil, electrical, industrial, mechanical, metallurgical, mining (mine)

**University of Oklahoma:** Architectural, civil, electrical, mechanical, petroleum (production option)

**Oklahoma Agricultural and Mechanical College:** Civil, electrical, industrial, mechanical

**Oregon State College:** Civil (excluding business option), electrical (excluding business option), mechanical (excluding business option)

**University of Pennsylvania:** Chemical, civil, electrical, mechanical

**Pennsylvania State College:** Architectural, chemical, civil, electrical, electrochemical, industrial, mechanical, sanitary

**University of Pittsburgh:** Chemical, civil, electrical, industrial, mechanical, metallurgical, mining, petroleum, petroleum refining

**Polytechnic Institute of Brooklyn:** Chemical (*h*), civil (*a*), electrical (*a*), mechanical (*a*)

**Princeton University:** Chemical, civil, electrical, mechanical

**Purdue University:** Chemical, civil, electrical, mechanical

**Rensselaer Polytechnic Institute:** Chemical, civil, electrical, mechanical

**Rhode Island State College:** Civil, electrical, mechanical

**Rice Institute:** Civil, electrical, mechanical

**University of Rochester:** Mechanical

**Rose Polytechnic Institute:** Civil, electrical, mechanical

**Rutgers University:** Civil, electrical, mechanical, sanitary

**University of Santa Clara:** Civil, electrical, mechanical

**South Dakota State College:** Civil electrical, mechanical

**South Dakota State School of Mines:** Civil, electrical, metallurgical, mining

**University of Southern California:** Petroleum

**Stanford University:** Civil, electrical, mechanical, metallurgical, mining, petroleum

**Stevens Institute of Technology** (*f*): General

**Swarthmore College:** Civil, electrical, mechanical

**Syracuse University:** Civil, electrical, industrial (administrative), mechanical

**University of Tennessee:** Civil, electrical, mechanical

**University of Texas:** Civil, electrical, mechanical, petroleum (petroleum production)

**Agricultural and Mechanical College of Texas:** Civil, electrical, mechanical, petroleum

**Texas Technological College:** Civil, electrical, mechanical

**Tufts College:** Civil, electrical, mechanical

**Tulane University of Louisiana:** Civil, electrical, mechanical

**Union College:** Civil, electrical

**University of Utah:** Civil, electrical, mechanical, metallurgical, mining

**University of Vermont:** Civil, electrical, mechanical

**University of Virginia:** Civil, electrical, mechanical

**Virginia Military Institute:** Civil, electrical

**Virginia Polytechnic Institute:** Civil, electrical, industrial, mechanical

**Washington University:** Architectural, civil, electrical, industrial (administrative), mechanical

**University of Washington:** Aeronautical, ceramic, chemical, civil, electrical, mechanical, metallurgical, mining

**State College of Washington:** Civil electrical (basic and hydroelectric, options), mechanical (basic option), metallurgical, mining (excluding mine administration and petroleum engineering option)

**Webb Institute of Naval Architecture:** Naval architecture and marine engineering

**West Virginia University:** Civil, electrical, mechanical, mining

**University of Wisconsin:** Chemical, civil, electrical, mechanical, metallurgical, mining

**Worcester Polytechnic Institute:** Civil, electrical, mechanical

**Yale University:** Chemical, civil, electrical, mechanical, metallurgical

(*a*). Accrediting applies to both the day and evening curricula.

(*b*). Accrediting applies to the 4-year and 5-year curricula leading to the bachelor of science degree.

(*c*). Accrediting applies to day curriculum only. Action on evening curriculum deferred pending granting of degrees.

(*d*). Accrediting applies to both regular and co-operative curricula.

(*e*). Accrediting applies only to curriculum as submitted to ECPD and upon completion of which a certificate is issued by Harvard University certifying that the student has pursued such a curriculum.

(*f*). The accrediting of a curriculum in general engineering implies satisfactory training in engineering sciences and in the basic subjects pertaining to several fields of engineering; it does not imply the accrediting, as separate curricula, of those component portions of the curriculum such as civil, mechanical, or electrical engineering that are usually offered as complete professional curricula leading to degrees in these particular fields.

(*g*). All curricula in agricultural engineering which appear in this list have been provisionally accredited for a period of 2 years. The reason for this is twofold; in the first place it appears to ECPD that the final year of the 4-year programs fails to build, in adequate manner, upon the engineering basis laid in the first 3 years; secondly, it is the feeling of ECPD that curricula in agricultural engineering might more properly be given as options under one of the major engineering branches (that is, civil engineering, electrical engineering, or mechanical engineering).

(*h*). ECPD has not received from its subcommittee on chemical engineering a recommendation with respect to the evening curriculum in chemical engineering.

*Cost of Lack of Guidance.* For lack of adequate guidance a considerable number of boys drop out at the end of or during the first year. There is a definite financial loss in each case. Much has been said about the intangible profit of going to college even one year. The statistics of engineers do not show tangible values for one or 2 years of college life. On the contrary, the moral and psychological effects of failure are serious and real. The sense of defeat is a handicap at a critical period in the life of youth struggling for a foothold.

Some 20,000 students, more or less, are asking admission to engineering colleges this fall. Two things should be done to prevent economic loss and to protect the engineering profession. First, there should be conscientious guidance provided by the schools, by colleges, and with the aid of the profession. Second, colleges should abandon competition for numbers and accept only those who can meet certain well-defined standards which promise a fair measure of achievement in engineering education and in their future business and professional careers.

## Report of Committee on Engineering Schools

Karl T. Compton, Chairman

The committee on engineering schools is expected, as its broad responsibility, "to formulate criteria for colleges of engineering, which will insure to their graduates a sound educational background for practicing the engineering profession." In order that the committee might carry out most effectively its broad program, the decision was made during its first year that the early efforts of the committee should be directed solely toward the accrediting of undergraduate curricula in engineering. There seemed to be a pressing need for a thoroughly representative and authoritative accrediting agency. While the committee recognized that the theoretical desirability of accrediting might be subject to considerable differences in opinion, it further recognized that various factors, including state licensing laws, were resulting in numerous unco-ordinated efforts to establish lists of accredited engineering colleges. In ECPD there seemed to exist an organization representing the entire profession, and thus ideally constituted to administer a plan for accrediting engineering curricula both uniformly and in a manner consistent with the high ideals of the engineering profession. (The basis for accrediting was published as part of report of the fourth annual meeting of ECPD in ELECTRICAL ENGINEERING for November 1936, pages 1280–5.)

In October 1936, an initial list of the curricula in 2 regions of the United States, judged by ECPD to be worthy of accrediting, was released for publication. Arrangements were made in the early spring of 1936 to extend the program into the remaining regions of the United States and to examine the institutions in the first 2 regions which had not applied in time for consideration during 1935–36. Ninety-five institutions submitted curricula, involving visits of inspection to 88 institutions during the year 1936–37. The remaining 7 institutions have asked for inspection during the year 1937–38.

*Summary of Institutions and Curricula Inspected.* Since the accrediting program was inaugurated in 1935, a total of 134 degree-granting engineering schools have submitted 642 curricula for accrediting. Of this number 127 institutions have been visited to date and recommendations prepared on 617 curricula. The records of the committee show that 20 degree-granting engineering colleges have not yet responded to the invitation of the committee.

*Summary of Recommendations.* The following is a summary of the actions recommended to ECPD by the committee for the 617 curricula inspected up to the present time:

| | |
|---|---|
| To accredit | 373 |
| To accredit provisionally for a limited period | 69 |
| To defer action | 35 |
| Not to accredit | 140 |
| Total | 617 |

Provisional accrediting has ranged from periods of one to 3 years and involves a revisit at the end of the period of accrediting. (In all other cases review is left entirely to the discretion of ECPD and its committee on engineering schools.) Deferred action has been taken where degrees have not yet been conferred, or where recommendations in regard to curricula in chemical engineering are still under consideration by the committee on chemical engineering education of the American Institute of Chemical Engineers. A complete list of the accredited curricula by institutions may be found elsewhere in this report.

*By-Products of Accrediting.* The main objective of the accrediting program, of course, has been to draw up a list of engineering curricula which, in the opinion of ECPD, represent sound and adequate instruction in the several branches of engineering. A second objective, however, has come to be regarded as being fully as important, namely, to be of the greatest possible aid to the institutions offering curricula for accrediting.

Almost without exception the visiting committees have been asked by the administrative officers of the institutions visited to give them suggestions and advice. The committees have endeavored to comply with these requests, and throughout the discussions of the regional committees, and of the general committee later, a great deal of attention has been given to the consideration of directions along which substantial improvements might be made which would increase the effectiveness of the teaching program of the institution. In many instances the opinion of the ECPD committee has been the deciding factor in making long-desired changes or improvements possible. In other cases the wide experience and fresh perspective of the delegatory committee members have made it possible to call to the attention of the officers of administration undesirable conditions which had remained unnoticed or neglected. That the suggestions of the committees have been appreciatively received may be seen both from the letters which have been written, and from the way in which the suggestions have been acted upon.

At present there is every indication that the accrediting program will result not only in a generally accepted accredited list, for which there is a real need, but also in a definite stimulation to higher excellence in our engineering schools, and a wide distribution among the institutions, particularly among the various officers of administration, of some of the best ideas in engineering education.

*Activities in Prospect.* Since the organization of the committee on engineering schools in 1932, attention has been focused almost solely upon the accrediting program. It has seemed recently that this project is now sufficiently well in hand to permit the consideration of other ways in which the committee could be of service. Accordingly, during the past year the committee has discussed several activities in which it might engage over a period of perhaps 5 years. Not all of these activities would, or could, be undertaken at once. Their possibilities are, however, being further studied, and the consideration of them will require a substantial portion of the committee's time during the ensuing year. These activities are:

(*a*). Continuation of accrediting program. The committee must necessarily make this its first concern. Plans for the periodic review and reinspection of accredited curricula were outlined roughly during the past year, and these will shortly be put into operation.

(*b*). Investigation of graduate study. The committee has recently considered this aspect of accrediting and come to the conclusion that there may be other more effective means of enhancing the status of graduate study.

(*c*). Study of admission with advanced standing. During the consideration of undergraduate curricula, it has become evident to the committee that the qualifications of an engineering student who transfers to an engineering school with advanced standing, in particular from an institution of a different type, such as a college of liberal arts or a junior college, are dependent to a considerable extent upon the quality of the instruction which he received in the institution from which he is transferring. It further is evident that the quality of work maintained at any institution is affected by the standards at other institutions which prepare students for entrance with advanced credit. It appears, therefore, to be within the scope of the committee to consider ways and means of improving standards at the junior colleges, colleges of liberal arts, other engineering schools, and divisions serving as feeders for institutions which have had curricula accredited by ECPD. A committee has been appointed to pursue the study of this problem.

(*d*). Advisory service to institutions. In view of the considerable experience and background which the delegatory committee members have gained during the course of the accrediting program, the committee should be in a position to be of material assistance to institutions offering engineering curricula by making available to interested institutions an informal advisory service. Recognizing that its experience creates a responsibility in this direction, the committee is prepared to perform such a function and is ready, on request, to advise or confer with representatives of engineering colleges in reference to any phase of their work related to accrediting.

(*e*). Survey of engineering education. During the course of its operations, the committee has assembled a great deal of valuable information on the status of engineering education. It appears highly desirable that this material be analyzed and published while it is yet fresh.

**Index to ASTM Proceedings.** A complete subject and author index covering the contents of volumes 31 to 35, inclusive, of the ASTM *Proceedings*, issued from 1931 to 1935, is now available from the American Society for Testing Materials, 260 South Broad Street, Philadelphia, Pa. Prices may be obtained from the society.

# Chemistry Subcommittee of NRC Insulation Committee Meets at Rochester

UNDER auspices of the physical and inorganic division of the American Chemical Society, at its annual convention at Rochester, N. Y., the subcommittee on chemistry of the insulation committee of National Research Council held a symposium on insulation materials, September 9, 1937. Kenneth S. Wyatt (A'32) research engineer for The Detroit (Mich.) Edison Company, and chairman of the subcommittee, who furnished the material from which this report was prepared, presided over the session, at which 5 papers were presented:

1. DIPOLE POLARIZATION AND DIELECTRIC LOSS IN CERTAIN LIQUIDS AND SOLIDS, S. O. Morgan, Bell Telephone Laboratories, Incorporated, New York, N. Y.

2. ELECTRIC BREAKDOWN OF SOLID AND LIQUID INSULATORS, A. von Hippel (M'37), Massachusetts Institute of Technology, Cambridge.

3. THE INFLUENCE OF GASEOUS ELECTRIC DISCHARGE ON HYDROCARBON OILS, L. J. Berberich (A'30, M'36) Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

4. METHODS OF MEASURING THE ELECTRICAL PROPERTIES OF SOLIDS, R. M. Fuoss, General Electric Company, Schenectady, N. Y.

5. ELECTRICAL AND CHEMICAL STUDIES OF OIL OXIDATION, J. C. Balsbaugh (A'23, M'25), Massachusetts Institute of Technology, Cambridge.

In a brief introductory outline of the objectives of the symposium Chairman Wyatt pointed out that "insulating materials find an extremely wide and indispensable place in the electrical industry, and that the development and research leading to improved insulating materials, the manufacture and processing of present materials, and the study of deterioration in service are to a large extent chemical problems. Yet the burden of the attack so far has rested on the shoulders of electrical engineers and physicists rather than chemists. To insure the most rapid progress it will be necessary to enlist to a greater extent the services of the chemists."

## TECHNICAL SESSION

*Dipole Polarizations and Dielectric Loss.* S. O. Morgan, in presenting his paper, asserted that although generally the function of dielectrics is considered to be the hindering of current flow from one conductor to another, or from a conductor to its surroundings, for many purposes the function of dielectrics is to permit the flow of alternating current.

"No insulator permits the flow of current without at least a small amount of energy being dissipated as heat. One of the tasks of the engineer is to obtain a maximum permittivity or dielectric constant with a minimum of dielectric loss. Dielectric theories predict that a high dielectric loss is a necessary consequence of a high dielectric constant. Experimental data for a wide variety of materials bear out this prediction."

Mr. Morgan described the relationships between the chemical composition and dielectric loss and dielectric constant and interpreted these quantities in terms of the motions of the electrons, atoms, and molecules making up the dielectric. The various kinds of motion are translational, vibrational, and rotational, and the motion of molecules containing electric dipoles influence both dielectric constant and dielectric loss of the material.

*Breakdown of Solid and Liquid Insulators.* A. von Hippel's paper showed that: "The extrapolation of Paschen's law from gases under normal pressure up to the high densities of solids and liquids would predict the field strength of electric breakdown in these condensed systems 10 to 100 times higher than observed. The main reasons for this discrepancy are the following: in gases of low density the excitation of the electronic system of the particles acts as the important barrier, which stops the acceleration of the electrons before they reach ionizing velocities. With tight packing of the atoms and molecules these excitation levels become practically destroyed and the excitation of vibrations remains as the decisive mechanism of friction. Hence the study of the excitation functions of vibrations is the most important step for the formulation of the theory of electric breakdown in condensed systems. Next, one has to consider changes of the field distribution and of the structure of the matter itself by charged particles. The field emission of the cathode plays a dominating part to lower the breakdown strength of insulators. Fragile material may crack by mechanical stresses, produced by changes of the particles forming the solid. Hence the total phenomenon is often a very complicated one and the simple theory of heat breakdown, widely accepted, seems to be inadequate."

*Influence of Gaseous Discharge on Hydrocarbon Oils.* "The new and revolutionary solvent-refining processes now rapidly being adopted by the whole oil industry make possible the production of better oils in most respects than was formerly possible," according to L. J. Berberich. "In the application of such oils to the insulation of high-voltage equipment, however, they were found to possess a serious disadvantage. It was discovered that they were vulnerable to attack by the gaseous electric discharges which occur unavoidably in some high-voltage apparatus. Through research it has been discovered that one class of hydrocarbon molecules, known as the aromatics, is particularly resistant to the action of the discharges, and now it has been found that this same class of hydrocarbons when added to the oil in small percentages reduces the formation of gases markedly. Thus again, a bit of knowledge is added which may result in the transmission of electric power more economically and reliably."

*Methods of Measuring the Electrical Properties of Solids.* "The essential difference from the point of view of measuring technique between solids and liquids is that the former do not in general give perfect electrical contact with metallic electrodes, which results in the presence of 2 large air capacitances in series with the unknown. A simple mathematical analysis shows that the film capacitances can produce serious experimental errors, which are dependent on the average thickness of the air film, the thickness of the sample, and the dielectric constant and conductance of the sample." R. M. Fuoss described several methods of eliminating such errors, using measurements on typical insulating materials as examples.

*Electrical and Chemical Studies of Oil Oxidation.* "One of the most important types of high-voltage insulation is the combination of oil and paper. During use, this insulation is subjected to elevated temperatures and high electrical stresses, so there are reactions of the various oil constituents among themselves, with traces of oxygen and water remaining in the cable and with the copper conductor and the lead sheath. One attack on this problem has been the investigation of oil oxidation. By the application of solvent refining methods to the oils, and by the addition of several tests to those now in common use, it is hoped that some new light may be shed on the entire problem. J. C. Balsbaugh discussed the relations between oxidation stability, acid formation, power factor, colloidal content, Grignard test, oil source, and refining methods. He further pointed out that many problems concerning the chemical and electrical aspects of this problem are still without any satisfactory explanation.

## DINNER MEETING

Following the symposium, which was attended by about 150 guests and members of the subcommittee, a dinner was held for the subcommittee, at which Doctor T. Smith Taylor (M'21) Diehl Manufacturing Company, Elizabethport, N. J., delivered an address on "Plastics for Electrical Insulation." At this dinner, held at the University Club in Rochester, about 80 people were present.

The joint meeting with the American Chemical Society seemed to direct much interest and enthusiasm toward the problems of insulation research. As a result, the subcommittee has received requests to hold similar symposia each year under the auspices of other divisions of the American Chemical Society.

**Diederichs, Engineering Dean, Dies.** Herman Diederichs, dean of college of engineering at Cornell University, Ithaca, N. Y., died August 31, 1937. Born at Muenchen-Gladbach, Germany, August 12, 1874, he was graduated from Cornell University in 1897 with the degree of mechanical engineer. The following year he became an instructor in experimental engineering at that university, and in 1902 was made assistant professor. Five years later he was appointed professor, and in 1921 became director of the school of mechanical engineering. Since 1936 he had been dean of the college of engineering. He was appointed John E. Sweet professor of engineering in 1928. Dean Diederichs was the author, with others, of several engineering books. He was a member of The American Society of Mechanical Engineers, Society of Automotive Engineers, American Society for Metals, and Verein deutscher Ingenieur; in 1930 he received the Melville Medal of the ASME.

## District 9 Award for Branch Paper

Prize for Branch paper in the AIEE North West District (No. 9) for the period from January to June 1937, inclusive, has been awarded to Thomas Y. Merrell and Edward A. Rich, Enrolled Students, for their paper "Investigation of Losses in Single-Phase Induction Motors," which was presented at a meeting of the University of Utah Branch on May 19, 1937. The award was made in accordance with the revision of prize rules recently adopted by action of the AIEE board of directors, by which the prizes for Branch papers are awarded on the basis of the academic year from July 1 to June 30, inclusive. Excerpts of the rules for prize awards were given in the April 1937 issue of ELECTRICAL ENGINEERING, page 492.

**Naval Architects to Meet.** The Society of Naval Architects and Marine Engineers will hold its 45th annual meeting at the Waldorf-Astoria Hotel, New York, N. Y., on November 18 and 19, 1937. Among the papers to be presented is "Ship Propulsion by the Emmet Mercury Vapor Process," by W. L. R. Emmet (A'93, M'94, HM'33, Edison Medallist '19, past vice-president, member for life). Other papers will discuss such subjects as the burning of fuel oil, fire control, United States Coast Guard cutters, and alloys in shipbuilding.

**ASME Elects Officers for 1938.** New officers for 1938 of The American Society of Mechanical Engineers were elected on September 28, 1937, and will assume office on December 10, 1937. They are: *President*—H. N. Davis, president, Stevens Institute of Technology, Hoboken, N. J. *Vice-Presidents*—F. O. Hoagland, master mechanic, Pratt and Whitney division, Niles Bement-Pond Company, Hartford, Conn.; B. M. Brigman (M'28) dean, Speed Scientific School, University of Louisville, Ky.; Harte Cooke, mechanical engineer, McIntosh and Seymour Corporation, Auburn, N. Y.; W. H. McBryde, consulting engineer, San Francisco, Calif.; L. W. Wallace, director, division of engineering research, Association of American Railroads, Chicago, Ill. *Managers*—Carl L. Bausch, vice-president, Bausch and Lomb Optical Company, Rochester, N. Y.; S. B. Earle, dean, school of engineering, Clemson Agricultural and Mechanical College, Clemson College, S. C.; F. H. Prouty, partner, Prouty Brothers Engineering Company, Denver, Colo.

## Co-operative Educational Program Announced

A co-operative educational enterprise which will link the Westinghouse Electric and Manufacturing Company and the Carnegie Institute of Technology in a new program of undergraduate engineering training was announced recently by President Robert E. Doherty (A'16, M'27) of Carnegie, formerly chairman of the AIEE committee on education. To make this project possible the Westinghouse company has appropriated $200,000 to the Carnegie Institute of Technology.

The new co-operative program, which will go into effect at the beginning of the next school year, will make it possible for a number of students with superior qualifications to take the usual technical courses for a degree at Carnegie, and, during the same period, to get extensive shop and engineering experience and training in the Westinghouse plant. Of the group of students who will be selected to follow the co-operative course, a number, perhaps 10 each year, will receive George Westinghouse scholarships. A George Westinghouse professorship of engineering also will be established, and one of the duties of the holder of this position will be the supervision of the co-operative program.

The program of study will cover 5 years, of which 4 academic years will be spent at Carnegie. The summer months and 2 college semesters, one in the third and one in the fourth year, will be spent at the Westinghouse plant. Of the students selected for the course, those designated as Westinghouse scholars will receive an income of $50 per month during the 5-year training period from the company. Students will pursue courses not only in electrical engineering, but in the other engineering branches as well. Applications for admission to the co-operative program will be received after January 1, 1938.

## Standards

**Test Code for Polyphase Induction Machines.** There is now available an approved edition of the "Test Code for Polyphase Induction Machines." This is the first of the test codes developed by the AIEE to receive formal approval. (The other codes, which are still in preliminary report form, are "Test Code for Transformers," "Test Code for Synchronous Machines," "Test Code for D-C Machines," and "Test Code for Apparatus Noise Measurement.") The purpose of these test codes is to provide in convenient reference form the more generally applicable and accepted methods of conducting and reporting tests of a commercial nature, which apply to the fulfillment of performance guarantees and to acceptance tests. Copies of the approved code, No. 500, can be obtained from AIEE headquarters at 50 cents each, with 50 per cent discount to AIEE members on single copies.

**Safety Code for Elevators.** In July 1937 the American Standards Association approved the revised fourth edition of the "Safety Code for Elevators, Dumbwaiters, and Escalators." This code of safety standards covers the construction, inspection, maintenance, and operation of elevators, dumbwaiters, escalators, and their hoistways with certain exceptions. This latest edition was prepared by a sectional committee fully representative of the building, manufacturing, insurance, governmental, and other interests. The committee was sponsored by the National Bureau of Standards, the American Institute of Architects, and The American Society of Mechanical Engineers. The code may be obtained through the ASME, 29 West 39th Street, New York, N. Y., at one dollar per copy.

**Manual for Inspection of Elevators.** In July 1937 the American Standards Association approved as American recommended practice an "Inspectors' Manual for the Inspection of Elevators." This manual is intended to serve as a guide for the general use of elevator inspectors and is based on the requirements of the "Safety Code for Elevators, Dumbwaiters, and Escalators." The manual may be obtained through The American Society of Mechanical Engineers, 29 West 39th Street, New York, N. Y., at 75 cents per copy.

## American Engineering Council

### AEC Annual Assembly and Conference of Secretaries

The eighteenth annual assembly of the American Engineering Council and the eighth annual conference of secretaries of engineering associations, clubs, councils, institutes, and societies in the United States are scheduled for January 13, 14, and 15, 1938. The meetings are to be held at the Hotel Mayflower in Washington, D. C. Problems of common concern to the engineering and allied technical professions are being considered by the committees, and the programs, which include the all engineers' dinner, are expected to hold unusual interest for all branches of engineering.

### AEC Committee on Merit System

A meeting of the committee on the merit system of American Engineering Council was held in New York, N. Y., September 16, 1937, on the call of Chairman R. L. Sackett. There were present A. W. Berresford (A'94, F'14, past-president, member for life), F. L. Bishop, H. H. Henline (A'19, M'26, national secretary), and J. C. Hoyt of the committee and F. M. Feiker (M'34), *ex-officio*. The committee concurred in the idea of devising ways and means of forwarding the merit system by preparing a plan of procedure whereby state and local societies could sponsor the merit system for employment of engineers in states and municipalities as well as to continue to forward, in the public interest, the general desirability of merit as a basis for federal employment.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or reject them entirely.

ALL letters submitted for consideration should be the original typewritten copy, double spaced. Any illustrations submitted should be in duplicate, one copy to be an inked drawing but without lettering, and other to be lettered. Captions should be furnished for all illustrations.

STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Synchronous Motor Effects in Induction Machines

*To the Editor:*

The effects noted by E. E. Dreese in the paper "Synchronous Motor Effects in Induction Machines" (AIEE TRANSACTIONS, July 1930, pages 1033–40) are not very common and, having run across a case of the same trouble, I believe it should be brought to the attention of induction-motor designers.

This case was brought up when several polyphase motors refused to come up to speed satisfactorily on production test. The rating was $^3/_4$ horsepower, 60 cycles, 220 volts, 4 poles, 1,725 rpm, 2 phase. The motors had 36 stator slots and 32 rotor slots, and were of normal design. Upon making careful investigation, it was discovered that the trouble was due to a synchronous cusp at 225 rpm, $^1/_8$ synchronous speed, similar to that described in the paper by Dreese.

Curve *A* of figure 1 shows the speed-torque characteristic of this motor. Curve *B* shows the same motor with the resistance rings turned smaller, and the air gap increased. Curve *C* shows the motor with a new rotor with more skew, but otherwise the same as the rotor of curve *B*.

One of the peculiar characteristics of this type of cusp was very definitely portrayed by these motors. If a motor has an ordinary induction cusp, such as would be shown by a curve similar to the dotted portion of curve *B*, it will not accelerate any load greater than that shown by the minimum torque point of the cusp. The synchronous cusp acts quite differently. If the synchronous goes to zero or negative, the motors seem to accelerate poorly even on light loads, but will usually come up to speed most of the time if several trials are made. If, however, the synchronous does not fall to zero, and has even half full load torque for a minimum value, the motor seems to accelerate very well. In fact, it is almost impossible to detect by ordinary starting and pull-up tests, that anything is wrong with the motor at all. On a number of motors which had a minimum point of 36 ounce-feet torque, all easily passed a minimum pull-up limit of 54 ounce-feet. Yet if the motors were allowed to slow down with a brake load of 38 ounce-feet, and the switch closed again when the speed had dropped very close to 225 rpm, they would all definitely lock in at the cusp, and refuse to accelerate again until the load was reduced to 36 ounce-feet.

Upon referring to page 1040 of Dreese's paper, we find that with

$$\frac{N \text{ (rotor slots)}}{p \text{ (poles)}} = \frac{32}{4} = 8$$

table II predicts a cusp at $^1/_{16}$ forward speed, and table III predicts one at $^1/_8$ backward speed, for 3-phase motors. However, upon referring to tables IV and V, for 2-phase motors, we find that $N/p = 8$ does not appear, and no cusp is expected.

On page 1041, C. J. Koch quotes P. L. Alger as finding that cusps would be expected at $p/N$ speed, and would be positive or negative depending on whether the motor were 3 or 2 phase, and whether the rotor or stator had the greater number of lots.

We then tested a similar 3-phase motor, and found a very pronounced cusp at −225 rpm as shown in figure 2. Again I wish to point out that in spite of the magnitude of this cusp, the motor would only lock in when the switch was closed at almost exactly this speed. The motor was loaded with considerable inertia load, and reversed time and time again, passing through the cusp speed quite slowly, and in no case would it lock in except when the switch was closed at just about the correct speed.

The rules of Alger seem to fit these 2 cases, whereas those of Dreese only partially

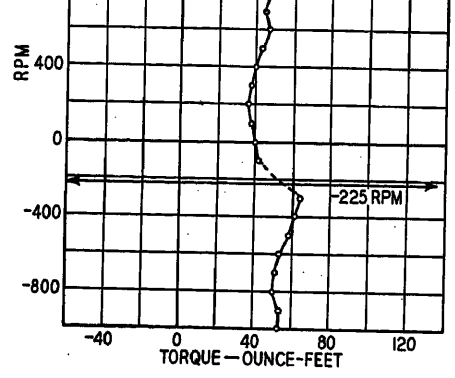


**Figure 2. Speed-torque curve of 3-phase motor**

Stator slots 36 Rotor slots 32

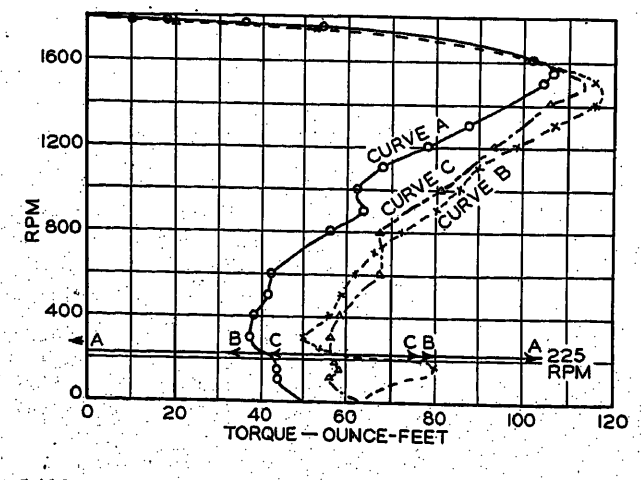

**Figure 1. Effect of air gap, skew, and rotor resistance on synchronous cusp of 2-phase motor**

| Stator slots 36 | Rotor slots 32 | | |
|---|---|---|---|
| Curve | Air Gap | Skew | $r_2$ |
| *A* | 0.020 | 0.313 | 2.48 |
| *B* | 0.030 | 0.313 | 3.25 |
| *C* | 0.030 | 0.500 | 3.25 |

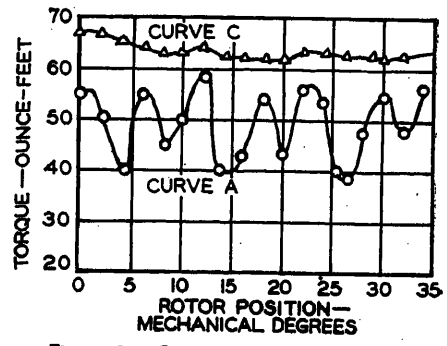

**Figure 3. Cogging of 2-phase motor**

| Stator slots 36 | Rotor slots 32 | | |
|---|---|---|---|
| Curve | Air Gap | Skew | $r_2$ |
| *A* | 0.020 | 0.313 | 2.48 |
| *C* | 0.030 | 0.500 | 3.25 |

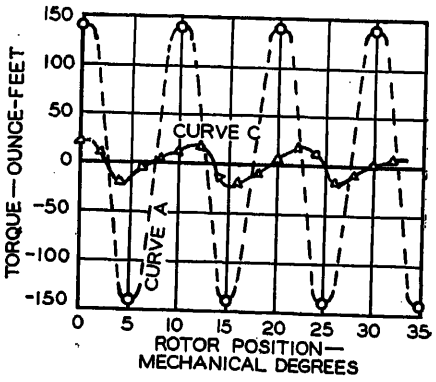

**Figure 4. Single-phase cogging of 2-phase motor with one phase open**

| Stator slots 36 | Rotor slots 32 | | |
|---|---|---|---|
| Curve | Air Gap | Skew | $r_2$ |
| *A* | 0.020 | 0.313 | 2.48 |
| *C* | 0.030 | 0.500 | 3.25 |

agree. We found the cusp at $^1/_8$ backward speed, but not at $^1/_{16}$ forward speed, and we did have the 2-phase case.

There was one other curious phenomenon which is illustrated in figures 3 and 4. The cogging or variation of starting torque with rotor position was very noticeable, particularly if one phase was opened. However, the cogging was practically eliminated by the changes which were made in air-gap, rotor resistance, and skew, whereas the synchronous cusp was not.

Very truly yours,

P. H. TRICKEY (A'30, M'36)
Design Engineer, Diehl Manufacturing Company, Elizabethport, N. J.

## Engineering Education and Democracy

*To the Editor:*

I have read with much interest R. E. Doherty's article entitled "Engineering Education and Democracy," in the September 1937 issue of ELECTRICAL ENGINEERING. This impressed me as being one of the most able articles by an engineer that I have read on this very important subject. The author certainly has discovered some of the principal underlying problems and has made some concrete suggestions for a solution.

Such a plan of broadening the education of engineering students and engineers is most commendable and, as he implies, some of our more energetic engineers have acquired something of the type of training, in one way or another, which he has so well described. The constructive point which I would like to raise in connection with the article is: Where are we to get the competent teachers to lead students to this broader outlook?

My own observations are to the effect that comparatively few men in the engineering profession, either in college or out of college, are prepared to furnish the leadership needed to carry forward such a splendid program as Doctor Doherty has outlined. Perhaps it will be necessary to start with the few who are capable as teachers and leaders and gradually develop a force of men trained to furnish this leadership.

All so-called educated people, including the professions, should give thought to the broad economic and governmental problems and it is encouraging to note that an increasing amount of thought and an increasing number of thoughtful articles by engineers are appearing in the various periodicals, and this in itself is a very encouraging sign.

Again expressing my appreciation for this splendid article, I am

Very truly yours,

J. L. HAMILTON (M'15, F'21)
Assistant to the General Manager, Century Electric Company, St. Louis, Mo.

*To the Editor:*

Robert E. Doherty's paper "Engineering Education and Democracy" strikes a responsive cord with me because he so ably has championed a program of engineering education which my colleagues and I have been endeavoring to carry out for more than a quarter of a century. Our program, first proposed and planned by Doctor George E. Hale, has been a great success even though it may be that some of us in our technical subject class rooms have failed to stress sufficiently the human side of engineering. Also, as I read Doctor Doherty's paper, I have been brought to realize that we, along with all others engaged in engineering, have been a bit slow in anticipating the need on the part of engineers for giving more "thought to consequences" which come about as a result of the technical development which has been so great during the last 1 or 2 generations. Indeed, I quite agree with President Doherty that, unless we are careful, there will be reason to become less optimistic about the outcome, for it is high time that we all gave heed to the idea conveyed by a statement which, more than 20 years ago, I once heard made by Doctor J. A. L. Waddell. The statement to which I refer is: "It is not difficult for me to find men who know how to build bridges, but it is tremendously difficult for me to find men who are able to determine whether or not the bridge should be built."

Referring, for purposes of illustration, to the sentence just quoted: As engineers we naturally, in trying to determine "whether the bridge should be built," apply first the laws of economics to see how the cost of the bridge may be paid. During the bad business period through which we have just been passing, we have learned that many persons use factors other than the rules of technical feasibility and economic value to arrive at a decision as to whether an engineering project shall be carried out.

In considering Doctor Doherty's comments concerning the balance between technical subjects content and humanities content in engineering course curricula, I am prompted to recall a striking incident in my own experience which, briefly summed up, resulted in the discovery of a mountaineer with eyes and hands so skillful that he was able to hew a true timber about 8 feet long and 3 by 4 inches in cross section, without the use of any tools other than an adz and an axe. Quite a contrast to the all-too-frequently-employed craftsman who comes with a trunk full of tools and can't turn out a true-surfaced board with square corners.

Good engineering is the measure of the man and not the measure of the number of tools in his kit. My 27 years of teaching experience makes me think that, on the whole, the man with a 4-year engineering course comprising a lot of what we have called the humanities (At California Institute of Technology 20 per cent of a student's time throughout the 4-year course and during the fifth year when the student is working toward the master's degree, is allotted to the study of what we call the humanities.) and which President Doherty has designated as the "social stem" is better prepared for life at the end of his college course than is the man who has given practically all his time during his 4-year college course to the study of technical subjects and to increased specialization. In fact I think such a course as has been described is the ideal education for any citizen of today whether he plans to be an engineer, a business man, or is preparing to engage in some other profession than engineering, such, for example, as the law, medicine, or the ministry. Curricula of this type naturally compel the prospective engineer to acquire most of his professional education after the regular 4-year college course has been completed; and I quite agree with Doctor Doherty that, for the majority of engineers, this follow-up professional education should be obtained in industry rather than by continuation in college. Such a conclusion, of course, is based on the assumption that industry will provide channels through which the student, as he works at being a junior engineer, can obtain the added education needed to make him, in his more mature years, a competent engineer.

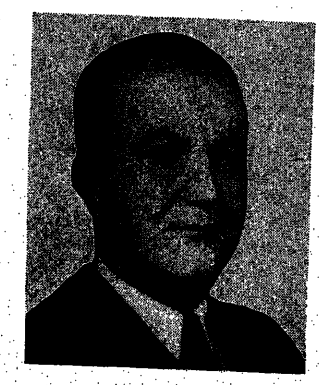
Doctor Doherty's 6 phases of education are excellent, but I think there should be an addition to the list of subjects given under number one, making that statement read, "a clear historical understanding of the parallel growths of religion and philosophy, of science and of engineering; because we should not forget that the primary value of a man in the engineering field, as in any other field of endeavor, is determined by that man's ability to live a righteous life whereby he may know how to use correctly the Golden Rule in all his relations with his fellow men." The educational program in which I have had a part has accomplished well the task of teaching all the 6 phases mentioned by Doherty, unless it be number 4, for I must admit that somehow no key has yet been found whereby the teacher may enable every student in his classes to use the English language effectively.

Near the end of his article Doherty has said that a program such as he has suggested may be considered by some as too expensive. Comparatively speaking, such a program is expensive if desired results are obtained, because the 6 points of a rounded education such as he has outlined can be effectively made a part of a student's life only by having the students come in close contact with men of real ability who themselves are examples of what proficiency in those 6 points can do. To do this there must be many teachers and small classes. Young men who have an interest in technical matters and plan to be engineers can be interested in literature and kindred subjects but the teachers of those subjects must be men of outstanding achievement who are inspired with enthusiasm for the subjects which they teach.

Doctor Doherty has concluded his paper with this question: "For what is to be gained by preparing engineers to continue their building of a physically magnificent structure only to have it torn down ultimately by the uncontrolled, unintelligent forces of selfish interests and vandalism?" I should like to supplement that question by another: Is it not the first duty of the engineer as a citizen of his country to make his first question regarding any project be "What does the construction of this project mean to the future of America when considered in the light of its whole influence upon us, our children, and our children's children?" If the answer to that question is satisfactory, then, and only then, has the engineer a moral right to proceed with the design and construction of the project.

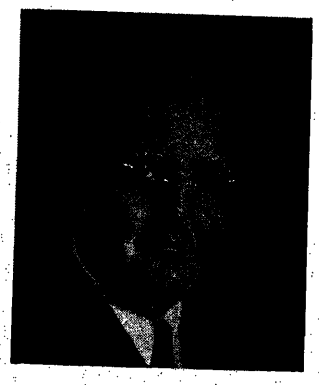
Very truly yours,

ROYAL W. SORENSEN
(A'07, F'19, director)
Professor of Electrical Engineering, California Institute of Technology, Pasadena



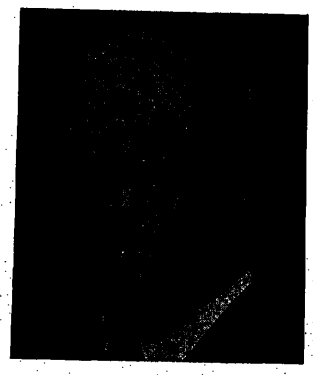
# Personal Items

E. E. DREESE (M'25) professor of electrical engineering and chairman of the electrical engineering department of The Ohio State University, Columbus, has been appointed chairman of the Institute's committee on basic sciences for the year 1937–38. Professor Dreese was born at Edmore, Mich., September 10, 1895, and was graduated from the University of Michigan in 1920 with the degree of bachelor of science in electrical engineering. In the following year he was appointed to the electrical engineering faculty of the University of Michigan as an instructor. At the same time he enrolled in the graduate school and in 1925 received the degree of master of science in electrical engineering, following which he was appointed chief engineer of the Lincoln Electric Company, Cleveland, Ohio. Professor Dreese remained with that company for 5 years, and during that time received the honorary degree of electrical engineer from the University of Michigan. In 1930 he was appointed professor of electrical engineering at The Ohio State University and made chairman of the department of electrical engineering. He is an active participant in the local affairs of the AIEE Columbus Section, and has been secretary (1933–34) and chairman (1934–35) of that Section; moreover, for the last 2 years he has been active in committee work of the Institute. He has been a member of the committee on basic sciences (formerly electrophysics) since 1935, and is entering his second year of service on the committees on education and student Branches. Professor Dreese is the author of 2 papers presented before the Institute. He is a member of the Society for the Promotion of Engineering Education, Tau Beta Pi, Eta Kappa Nu, and Sigma Xi.



WILLS MACLACHLAN (A'08, F'21, past vice-president) consulting electrical engineer, Toronto, Ont., Canada, has been appointed to serve as chairman of the Institute's committee on safety for the term 1937–38. Mr. Maclachlan was born August 3, 1885, in Toronto, and received the degree of bachelor of applied science at the University of Toronto in 1907. For one year following his graduation he was employed by the Canadian Westinghouse Company as erection engineer before becoming electrical superintendent of the Dominion Government Grain Elevator at Port Colborne, Ont. After serving other companies in various positions from 1910 until 1913, he was appointed engineer-in-charge of the Electric Power Company, Toronto, in the latter year, and remained in that capacity until 1915, when he became inspector for the Electrical Employers Association of Ontario. Mr. Maclachlan's work for that association has been continuous, and has been concerned with accident prevention in several private and municipal utility companies. Since 1917 he has been consultant on employee relations to the Hydro Electric Power Commission of Ontario and has served as Safety adviser to several other organizations in Ontario. Mr. Maclachlan was vice-president of the Institute during 1919–20, served as a member of the committees on mines (now applications to mining work), 1919–20, and law (now constitution and by-laws), 1920–21. He has been a member of the committee on safety since 1920, and during 1920–21 was a member of the special committee on geographical division and election procedure. Mr. Maclachlan has been active in the committee and administrative work of other organizations, including the former National Electric Light Association, Edison Electric Institute, National Safety Council, Canadian Engineering Standards Association, Canadian Electrical Association, Royal Canadian Institute, and others, and is the author of many papers and articles dealing principally with electric shock and remedial measures.

A. M. MACCUTCHEON (A'12, F'26, junior past-president) engineering vice-president of the Reliance Electric & Engineering Company, Cleveland, Ohio, has been appointed chairman of the Institute's committee on Institute policy for the term 1937–38. Mr. MacCutcheon was born at Stockport, N. Y., December 31, 1881, and was graduated from the State Normal College at Albany in 1901. After teaching mathematics and science in high schools until 1904 he entered the electrical engineering school at Columbia University and was graduated in 1908. From 1909 until 1914 he was affiliated with the Crocker-Wheeler Company, Ampere, N. J. In 1914 he took charge of all new design work of the Reliance Electric & Engineering Company, was appointed chief engineer in 1917, and in the fall of that year entered the United States Navy. Following his release in 1919 he returned to his former position, and in the following year was elected a director of the Reliance company. Since 1923 Mr. MacCutcheon has held the position of vice-president in charge of engineering. He was a director of the Institute from 1928 until 1932, president during 1936–37, and has served as a member of the following committees: general power applications, 1916–18, 1924–33 (chairman 1925–28); electrical machinery, 1924–34; meetings and papers (now technical program) 1925–29; electric welding, 1928–30; applications to iron and steel production, 1928–33; Edison Medal, 1929–31; executive, 1930–31; standards, 1922–36 (chairman 1931–34) and Lamme Medal, 1934–37 (chairman 1935–36). He is now a member of the executive committee and the Edison Medal committee, and is the Institute's representative on the United States National Committee of the International Electrotechnical Commission, the electrical standards committee of the American Standards Association, the standards council of the same organization, and the John Fritz Medal board of award. Mr. MacCutcheon is a member of several technical and engineering organizations.



W. M. YOUNG (A'24, M'34) formerly research engineer for the Taylor Instrument Companies, Rochester, N. Y., has been appointed dean of the college of applied science of Ohio University, Athens. Doctor Young was born August 17, 1898, at Omaha, Nebr., and received the degrees of bachelor of science in electrical engineering (1921), master of science in electrical engineering (1922), and doctor of philosophy (1926) at the University of Illinois. Following his graduation in 1921 he was appointed assistant in the physics department of the University of Illinois, where he taught electrical measurements until he had completed his graduate studies. In 1926 he was appointed to the faculty of the Texas Technologic College, Lubbock, as adjunct professor of general and engineering physics, but in the following year was transferred to the electrical engineering department as associate professor. Doctor Young became associate professor of electrical engineering at the University of Iowa in 1930; however, he remained there only one year before leaving the teaching

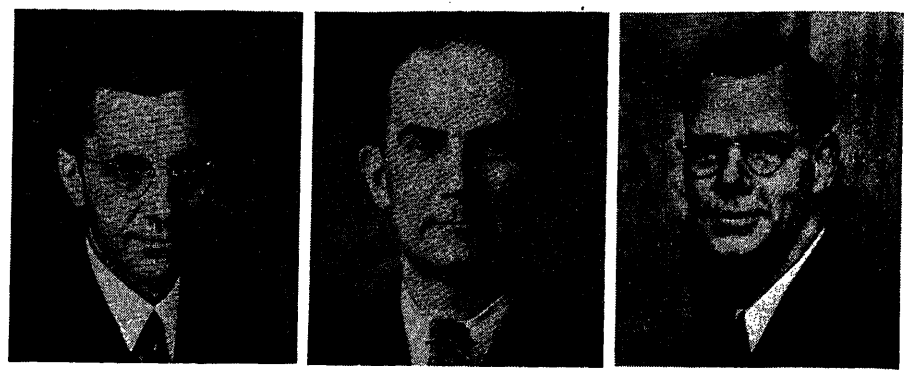
ROBIN BEACH

profession to become a research engineer for the Taylor Instrument Companies, in which capacity he has been engaged in the derivation of electrical control instruments for application to industrial processes. He has made numerous contributions of articles and papers to technical and professional journals, and is a member of the American Physical Society, Society for the Promotion of Engineering Education, Tau Beta Pi, Sigma Xi, and Eta Kappa Nu.

ROBIN BEACH (A'15, F'35) professor and head of the department of electrical engineering, Polytechnic Institute of Brooklyn, Brooklyn, N. Y., has been appointed chairman of the Institute's committee on production and application of light for the year 1937–38. Professor Beach was born at Robin's Island, N. Y., August 30, 1889, and received the degrees of bachelor of science in electrical engineering (1913) and electrical engineer (1922) at New Hampshire University. In 1922 he received also the degree of master of science at New York University. Following his graduation in 1913 he served briefly as an instructor in engineering drawing and descriptive geometry at the University of Illinois, but in 1914 became assistant professor of electrical engineering at the Texas Agricultural and Mechanical College and was placed in charge of the development of an electrical measurements laboratory at that school. In 1917 Professor Beach was appointed head of the department of electrical engineering at Norwich University, Norwich, Vt., but remained there for only one year before being appointed to the electrical engineering faculty of the Brooklyn Polytechnic Institute as associate professor. In 1927 he received his full professorship, and in 1930 was appointed head of the department. He has been a member of the Institute's committees on education and production and application of light since 1935 and previously served on the latter committee during 1933–34. He is Institute representative on the United States National Committee of the International Commission on Illumination. Professor Beach is a member of the Society for the Promotion of Engineering Education.



E. L. PHILLIPS (A'26) has retired from the presidency of the Long Island Lighting Company, New York, N. Y., to become chairman of the board of the company. Mr. Phillips was born at Naples, N. Y., March 1, 1873, and was graduated from Cornell University in 1895 with the degree of mechanical engineer, following which he entered the employ of the DeLaval Separator Company as a draftsman. In the following year he transferred his affiliation to the Sprague Electric Company, where he served in a similar capacity as draftsman and designer. Mr. Phillips became associated with Westinghouse, Church, Kerr, and Company, a consulting engineering firm in New York, as engineer in charge in 1897. He remained with that organization for 8 years until he established his own consulting engineering firm in 1905 under the name of E. L. Phillips and Company, with headquarters in New York. For many years he conducted a consulting and contracting business in New York and devoted much of his activity to the construction, expansion, and operation of public utility companies. Mr. Phillips was one of the founders of the Long Island Lighting Company in 1911 and held the position of president of that company for more than 25 years; however, at various times he served as president of the Empire Power Corporation and the Kings County Lighting Company and as chairman of the board of Queens Borough Gas and Electric Company, United Gas and Electric Corporation, and United Gas Engineering Company. He is a member of The American Society of Mechanical Engineers.

E. S. LEE (A'20, F'30, past director) engineer in charge of the general engineering laboratory, General Electric Company, Schenectady, N. Y., has been appointed chairman of the Institute's committee on transfers for the year 1937–38. Mr. Lee, who was born at Chicago, Ill., November 19, 1891, was graduated from the University of Illinois in 1913. He then became an instructor in electrical engineering at Union College and there earned the degree of master of science in electrical engineering, which he received in 1915. Since 1918 he has been affiliated continuously with the General Electric Company, becoming assistant engineer of the general engineering laboratory in 1928 and being appointed to his present position in 1931. Mr. Lee, a past chairman of the AIEE Schenectady Section, has served on many of the Institute's committees: finance, 1933–37 (chairman 1936–37); co-ordination of Institute activities, 1930–33, 1936–37; headquarters, 1936–37; and executive, 1933–37. He has been a member of the committee on instruments and measurements since 1927 (chairman 1927–30) and of the membership committee (chairman 1933–36) since 1933. He has served as Institute representative for the division of engineering and industrial research of the National Research Council, and was director of the Institute from 1933 until 1937. Mr. Lee is the author of numerous technical papers. He has been active in committee work of The American Society of Mechanical Engineers, American Society for Testing Materials, and American Standards Association.

W. E. CRAWFORD (M'28, F'36) consulting engineer, A. O. Smith Corporation, Milwaukee, Wis., has been appointed chairman of the Institute's committee on electric welding for the year 1937–38. Mr. Crawford was born August 21, 1889, at Big Rapids, Mich., and was graduated from the University of Michigan in 1914 with the degree of bachelor of science in electrical engineering. From 1911 until 1917 he taught physics in Michigan high schools, but in 1914 undertook electrical and power survey work for the German American Sugar Company, Bay City, Mich., concurrently with his teaching activities. After serving briefly as assistant chief engineer of the Republic Truck Company, Mr. Crawford became chief engineer of works of the Duplex Truck Company, Lansing, Mich., and remained in that capacity until 1919, when he became consulting engineer to the Mitchell Motors Company. One year later he became plant engineer for the A. O. Smith Corporation; in 1926 he was appointed consulting engineer to that organization and has been retained in that capacity continuously. He has been a member of the Institute's committee on electric welding since 1933. He is a member and past-president of the Milwaukee Welding Society and a member of the American Welding Society.

C. P. RANDOLPH (M'17) chief engineer of the Edison General Electric Appliance Company, Inc., Chicago, Ill., has been elected vice-president of the company. Mr. Randolph was born at Austin, Texas, December 30, 1888, and received the degrees of bachelor of arts (1908) and master of arts (1909) at the University of Texas. In 1909 he enrolled in the graduate school of Massachusetts Institute of Technology, and in the following year was appointed a research associate in chemical engineering. During 1911–12 he was an assistant to William Stanley

(A'87, M'98, F'13, Edison Medalist'12, past vice-president) in evolving electric heating apparatus for the General Electric Company, Pittsfield, Mass., following which he was placed in charge of experimental work on heating devices and later made managing engineer of the heating device department of that company. When the heating device department of the General Electric Company was consolidated with the Hughes Electric Heating Company and the Hotpoint Company to form the Edison General Electric Appliance Company, Inc., in 1928, Mr. Randolph went to Chicago to become chief engineer of the new company.

C. P. RANDOLPH J. B. THOMAS R. L. KINGSLAND

R. L. KINGSLAND (M'14) electrical engineer, Consolidation Coal Company, Inc., Fairmont, W. Va., has been appointed chairman of the Institute's committee on applications to mining work for the year 1937–38. Born May 15, 1882, at Nutley, N. J., Mr. Kingsland was graduated from Cornell University in 1905, and immediately after graduation entered the employ of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., as an engineering apprentice. In 1907 he was transferred to the turbine testing department of the Westinghouse company, but later in the same year became superintendent of motive power of the Pittsburgh and Butler Street Railway Company. From 1908 until 1909 Mr. Kingsland again served the Westinghouse company in several positions, until he became electrical engineer for the Consolidation Coal Company. His affiliation with that company has been continuous since 1909, during which time he has been assistant superintendent of the power and mechanical department, superintendent of the power and mechanical department, and electrical engineer. Mr. Kingsland has been a member of the Institute's committee on applications to mining work since 1916, and served on the committee on protective devices from 1927 until 1929.

R. D. MCMANIGAL (A'18) assistant department manager of the Westinghouse Electric International Company, New York, N.Y., recently was appointed manager of the central station and transportation division of the company. Mr. McManigal joined the Westinghouse company in 1915 after graduation from Lafayette College with a degree in electrical engineering. After completing the company's student training course he was transferred to the general engineering department, where he remained for 7 years, with the exception of a period of service in the United States Navy during the World War. In 1922 he went to Japan as railway specialist for the Westinghouse Electric International Company, and later became managing director of the Westinghouse Electric Company of Japan. In 1931 he returned to the United States to become assistant department manager.

J. B. THOMAS (M'28) vice-president of the Texas Electric Service Company, Fort Worth, has been appointed chairman of the Institute's committee on legislation affecting the engineering profession for the term 1937–38. Mr. Thomas was born July 19, 1891, at San Marcos, Texas, and received the degree of bachelor of science in mechanical engineering at the Texas Agricultural and Mechanical College in 1911, following which he held various positions for brief periods before becoming affiliated with the Texas Power and Light Company, Dallas, first as a draftsman and later as an office engineer. During the World War he served in the United States Army Coast Artillery Corps, and at the end of the War returned to the Texas Power and Light Company as resident engineer in 1919; later he became office engineer and assistant chief engineer before being appointed chief engineer of that company in 1921. Mr. Thomas became vice-president of the Texas Electric Service Company in 1930. He has been a member of the Institute's committee on legislation affecting the engineering profession since 1931 and is at present a member of the committee on general power applications. He was a member of the special committee on the engineering profession during 1930–31. Mr. Thomas is a member of The American Society of Mechanical Engineers.

SIDNEY HOSMER (A'97, F'12, member for life) vice-president and general manager of the Edison Electric Illuminating Company of Boston (Mass.), has retired from active service. He was born July 13, 1871 in London, England, and after being graduated from Yale University in 1892 entered the employ of the Mather Electric Company, Manchester, Conn. In 1894 he was made superintendent of the underground cable department of the Boston Electric Light Company, and when that company was merged with the Edison Electric Illuminating Company of Boston, Mr. Hosmer was made superintendent of construction. He was elected a vice-president in 1926 and in 1932 became general manager and a director.

B. M. BRIGMAN (M'28) dean of the Speed Scientific School, University of Louisville (Ky.), recently was elected a vice-president of The American Society of Mechanical Engineers for the year 1937–38. Dean Brigman, born February 25, 1881, at Louisville, attended the University of Kentucky, received the degrees of bachelor of science (1908) and master of science (1912) at the University of Louisville, and studied in the graduate school of the University of Wisconsin. After teaching in Louisville high schools for several years, he joined the teaching staff of the University of Louisville in 1912, where he has remained since. In 1923 he organized the Speed Scientific School of that institution and was made its dean, a position he has held continuously.

A. A. ATKINSON (A'07, M'27) dean of the college of applied science and professor of electrical engineering and physics at Ohio University, Athens, since 1893, has retired. Dean Atkinson was born March 7, 1867, at Nelsonville, Ohio, and received the degree of bachelor of science at Ohio University in 1892. Following one year of graduate study (1892–93) at the University of Michigan he returned to Ohio University and received the degree of master of science in 1895 while serving on the faculty of that institution as associate professor of physics. He is a member of the American Association for the Advancement of Science and the American Physical Society.

E. W. KIMBARK (A'27, M'35) formerly an assistant in electrical engineering at Massachusetts Institute of Technology, Cambridge, now is assistant professor of electrical engineering at the Polytechnic Institute of Brooklyn, Brooklyn, N. Y. Professor Kimbark is a native (1902) of Chicago, Ill., and received the degrees of bachelor of science (1924) and electrical engineer (1925) at Northwestern University, following which he entered the graduate school of Massachusetts Institute of Technology and obtained the degree of master of science in electrical engineering in 1933. He was appointed to the staff of that institution in the following year.

W. H. GEIGER (A'12) assistant superintendent of the Bergen division, Public Service Electric and Gas Company, Hackensack, N. J., has been promoted to superintendent of that division. Mr. Geiger, a native (1881) of Brumfieldville, Pa., was graduated from the Keystone State Normal School of Pennsylvania in 1904 and from Lehigh University in 1908. Immediately after his graduation in 1908 he became affiliated with the Public Service Electric and Gas Company, where he has spent his entire professional career. He was assistant superintendent of the Bergen division for 18 years.

C. L. DUDLEY (A'23, M'29) assistant distribution engineer in the electrical distribution department of the Public Service Electric and Gas Company, Newark, N. J., has been made southern division superintendent of that company's electrical distribution department, with headquarters at Trenton, N. J. Mr. Dudley was born at North Branford, Conn., in 1899, and is an electrical engineering graduate of Yale University. He has served in the distribution department of the Public Service company for more than 17 years.

VICTOR SIEGFRIED (A'32) instructor in electrical engineering at Worcester Polytechnic Institute, Worcester, Mass., has been made assistant professor of electrical engineering. Professor Siegfried, a native (1909) of Seattle, Wash., and an electrical engineering graduate of Stanford University, has been on the teaching staff of Worcester Polytechnic Institute since 1933. He is author or co-author of several papers presented before the AIEE, the latest of which appeared in the October 1937 issue of ELECTRICAL ENGINEERING, pages 1285–9.

T. Y. MERRELL (Enrolled Student) has received the AIEE North West District prize for Branch paper with E. A. Rich (Enrolled Student) for their paper "Investigation of Losses in Single-phase Induction Motors," presented at a meeting of the University of Utah Branch, May 19, 1937. Mr. Merrell was born December 27, 1914, at Brigham City, Utah, and received the degree of bachelor of science at the University of Utah in 1937.

L. H. FOX (A'31, M'36) who has been associate professor of electrical engineering at Mississippi State College, State College, Miss., now is a member of the development department of Ward Leonard Electric Company, Mount Vernon, N. Y. A native of Fox, Miss., he is an electrical engineering graduate of Mississippi State College and Massachusetts Institute of Technology, and has been a member of the faculty of the former institution since 1930. He is a member of Tau Beta Pi and the Society for the Promotion of Engineering Education.

C. C. LONG (A'14, M'30) until recently mechanical and electrical construction engineer, Riegos y Fuerza del Ebro, Barcelona, Spain, now is senior electrical engineer of the Metropolitan Water District of Southern California, Los Angeles. Mr. Long previously was in Spain (1920–22), following which he was an electrical engineer in the department of engineering design of the Southern California Edison Company, Los Angeles, until 1930.

C. L. CHATHAM (A'25, M'32) electrical distribution department, Public Service Electric and Gas Company, Newark, N. J., has been made assistant distribution engineer. He is a graduate of Massachusetts Institute of Technology and has been with the Public Service company since 1922. Upon completion of a cadet engineering course he was assigned to the Passaic (N. J.) division and was transferred to the Newark offices in 1926.

E. A. RICH (Enrolled Student) has received the AIEE North West District prize for Branch paper with T. Y. Merrell (Enrolled Student) for their paper "Investigation of Losses in Single-Phase Induction Motors," presented at a meeting of the University of Utah Branch, May 19, 1937. Mr. Rich was born March 30, 1916, at Salt Lake City, Utah, and received the degree of bachelor of science at the University of Utah in 1937.

T. S. SLOAN (A'21, M'33) for the last 9 years manager of the Rome division of the Georgia Power Company, has been appointed to direct company operations in southwestern Georgia. Prior to his affiliation with the Georgia Power Company, Mr. Sloan was associated with the Central Georgia Power Company in various capacities for more than 12 years.

E. A. CHILDERHOSE (M'37, F'37) senior engineer, Federal Power Commission, New York, N. Y., has resigned to join the staff of Jackson and Moreland, consulting engineers, Boston, Mass. Mr. Childerhose will be in charge of electrical engineering on new projects coming under the supervision of that company.

W. F. JACOB (A'35) librarian of the General Electric Company, Schenectady, N. Y., and a former member of the Engineering Societies Library staff, recently was elected president of The Special Libraries Association. He served that organization previously as vice-president.

C. L. COLLENS (A'07) president of the Reliance Electric & Engineering Company, Cleveland, Ohio, has been elected to membership on the board of directors of the American Standards Association. Mr. Collens is active in the work of the National Electrical Manufacturers Association also.

J. S. JOHNSON (A'37) instructor in the department of theoretical and applied mechanics at Iowa State College, Ames, who received the degree of doctor of philosophy at that school recently, has become an instructor in electrical engineering at the Missouri School of Mines and Metallurgy, Rolla.

W. O. RAY (A'35) instructor in electrical engineering at the Texas Agricultural and Mechanical College, College Station, was appointed this fall to the electrical engineering department of the Michigan College of Mining and Technology, Houghton.

R. J. W. KOOPMAN (A'36) who has been an instructor in electrical engineering at Michigan College of Mining and Technology, Houghton, now is a member of the electrical engineering faculty of the University of Kansas, Lawrence.

H. T. KOHLHAAS (A'07, M'19) editor of *Electrical Communication*, a publication of the International Telephone and Telegraph Company, New York, N. Y., has been transferred to London, England, where that periodical now is being published.

R. E. THOMPSON (M'34) formerly mechanical engineer for the Federal Light and Traction Company, New York, N. Y., now holds a similar position with the Albuquerque (N. M.) Gas and Electric Company.

E. J. POITRAS (A'33) formerly director of research, Ford Instrument Company, Inc., Long Island City, N. Y., now is employed by the Lombard Governor Corporation, Ashland, Mass.

W. F. RAMSAY (A'30) recently was employed as a draftsman for Gibbs & Cox, Inc., marine architects and engineers, New York, N. Y.

E. J. WHEELER (A'35) asistant engineering aide, U.S. Biological Survey, San Antonio, Texas, has been made engineering aide and transferred to Denver, Colo.

W. R. UFFELMAN (A'34) sales engineer for the Clark Controller Company, Detroit, Mich., has been transferred to the Cleveland, Ohio, offices of that company.

H. F. TINCOMBE (A'36) has been appointed assistant electrical superintendent of the Canadian Johns-Manville Company, Ltd., Asbestos, Que.

J. H. ANDERSON (A'36) recently affiliated himself with the Electro-Motive Corporation, LaGrange, Ill., as a junior engineer.

F. P. WEISS (A'36) recently entered the employ of the Carnegie-Illinois Steel Corporation, Gary, Ind., as a test engineer.

W. B. RENTON (A'34) recently was appointed resident engineer for the H. J. Heinz Company, at Medina, N. Y.

G. N. BROWN (A'36) recently was employed by the Western Electric Company, Chicago, Ill., as an equipment engineer.

# Obituary

HENRY WRIGHT FISHER (A'95, M'01, F'12, member for life) retired consulting engineer for the General Cable Corporation, Perth Amboy, N. J., died near Asheville, N. C., October 7, 1937. Mr. Fisher was born January 31, 1861, at Youghal, Ireland, and was graduated from Cornell University with the degree of mechanical engineer in the class of 1888. After graduation he held one or 2 minor positions before joining the staff of the Standard Underground Cable Company, remaining with that firm until 1927, when it became a part of the General Cable Corporation and he was retained on the engineering staff of the new organization. He was chief electrical engineer of the Standard Underground Cable Company from 1889 to 1915, manager of the lead cable and rubber works from 1915 to 1923, technical director of electrical engineering from 1923 to 1927, and for one year thereafter with the General Cable Corporation, and consulting engineer from 1928 to 1930, when he retired. Mr. Fisher held patents on several improvements in cable construction and methods of locat-

ing faults in underground cables, and during the World War was one of a staff of engineers acting in an advisory capacity to the government. He served the Institute as a member of the committees on standards (1914–22) and power transmission and distribution (1915–19) and was a member of the United States National Committee of the International Electrotechnical Commission from 1919 until 1926. He was a member of the American Society for Testing Materials, American Electrochemical Society, and Sigma Xi.

KAY AXEL CHRISTIANSEN (F'37) chief engineer of the Administration of Danish Posts and Telegraphs, Copenhagen, Denmark, died July 13, 1937. Mr. Christiansen was born May 1, 1891, in Copenhagen, and received his technical education in that city, where he was graduated in 1917 as diploma engineer at the Polytechnic Institute. He entered the communications branch of electrical engineering almost immediately, and from 1919 until 1923 he worked for several telephone companies in the United States. During 1923 he entered the service of the Administration of Danish Posts and Telegraphs and became its chief engineer and head of the radio service in 1926. In that capacity he participated in the activities of the International Telephone Consultative Committee, International Consultative Committee on Radio, and the International Radio Union. In 1931 he was president of the second plenary meeting of the committee on radio at Copenhagen.

THEODORE BLACKWELL MORGAN (A'21, M'21) southern division superintendent of the Public Service Electric and Gas Company, Trenton, N. J., died September 25, 1937. Mr. Morgan was born at Morgan, N. J., in 1881, and attended Pratt Institute and the Polytechnic Institute of Brooklyn. In 1899 he entered the employ of the Electrical Testing Laboratories, Harrison, N. J., and in 1902 became a helper in the electrical laboratories of the New York Edison Company, Inc., New York, N. Y. He remained with the latter company until 1907, when he was placed in charge of the electrical laboratories of the Brooklyn (N. Y.) Rapid Transit Company. From 1909 until 1920 Mr. Morgan was associated with the Connecticut Electric Light and Power Company, and held various positions in that company until he was appointed assistant superintendent of the southern division of the Public Service Electric and Gas Company in 1920. He became division superintendent in 1928.

DAVID COBURN BACON (A'28) building and equipment engineer, Southwestern Bell Telephone Company, Dallas, Texas, died August 22, 1937. Mr. Bacon was born September 22, 1884, at Jaffrey, N. H., and was graduated from Worchester Polytechnic Institute with the degree of bachelor of science in electrical engineering. In 1909 he joined the plant department staff of the American Telephone and Telegraph Company, but 2 years later was transferred to the traffic department of the Southwestern Bell Telephone company. After 9 years in the traffic department he was made building and equipment engineer in the engineering department, a position he held continuously for 17 years.

LUCIUS FOY DEMING (A'11) district engineer for the General Electric Company, Philadelphia, Pa., died recently. Mr. Deming was born February 11, 1876, at Amboy, Ill., and was graduated from Yale University in the class of 1896. He became affiliated with the General Electric Company soon after his graduation and never relinquished his position with that company during more than 40 years of active professional service. His first position was in the testing department of the General Electric Company; later he became a d-c designer, a rotary converter designer, and in 1906 district engineer.

BANKA BEHARI ROY (A'31) power station superintendent, Ahmedabad (India) Electricity Company, Ltd., died several months ago, according to word just received at Institute headquarters. Mr. Roy was born September 14, 1889, at Dakshinpaiksha, India, and attended Calcutta University, following which he received practical training in electrical engineering as a general assistant for the British Engineering Company, Calcutta, and later was employed by several railway companies in India. He became power station superintendent of the Ahmedabad Electricity Company in 1929.

MILTON M. GESS (A'34) electrical engineer, Battery Equipment and Supply Company, Chicago, Ill., died August 25, 1937. Mr. Gess was born December 18, 1909, at Dolton, Ill., and was graduated from Armour Institute of Technology with the degree of bachelor of science in electrical engineering in 1929, following which he became a testman, and later electrical engineer for the Battery Equipment and Supply Company.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting on October 14, 1937, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

**To Grade of Member**

Conlon, F. B., development engineer, Airtemp Inc., Dayton, Ohio.
Endicott, William, general assistant, General Electric Company, Minneapolis, Minn.
Gaskins, Richard W., electrical engineer, Union Electric Company of Illinois, St. Louis, Mo.
Meyerand, R. G., electrical engineer, Union Electric Company of Missouri, St. Louis.
O'Neill, O., assistant engineer, Consolidated Edison Company of New York, Inc., New York, N. Y.
Parker, L. H., electrical engineer, Turlock Irrigation District, Turlock, Calif.
Polster, M. A., assistant to superintendent, electrical distribution department, Consolidated Gas, Electric Light and Power Company of Baltimore, Baltimore, Md.
Shoffner, J. R., electrical and chief engineer, Allegheny River Mining Company; Reid Coal Company; Ringgold Coal Company; Ringgold Corporation, Timblin, Pa.
Spencer, T. A., member technical staff, Bell Telephone Laboratories, Incorporated, New York, N. Y.
Wolf, H. B., maintenance foreman, Duke Power Company, Charlotte, N. C.

**10 to Grade of Member**

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the national secretary before November 30, 1937 or January 31, 1938, if the applicant resides outside of the United States or Canada.

Abramson, L. Z., Gibbs & Hill, New York, N. Y.
Bailey, R. E., Utah Power & Light Co., Park City, Utah.
Belkin, E. I., 1166 Manor Avenue, New York, N. Y.
Brandenstein, E. W. (Member), General Electric Co., Erie, Pa.
Burnham, R. F., Connecticut Power Company, Stamford, Conn.
Carter, H. E. (Member), Duke Power Co., Charlotte, N. C.
Carter, L. T. (Member), General Electric Company, New York, N. Y.
Cohen, LeR. D., Tennessee Valley Authority, Wilson Dam, Ala.
Dayton, C. S., Jr., Safety Car Heating and Lighting Company, New Haven, Conn.
Deardorff, H. E., Dayton Power and Light Company, Dayton, Ohio.
Dellamano, F. J., Consolidated Edison Company of New York, Inc., New York, N. Y.
Douglass, W. E. (Member), Monongahela West Penn Public Service Company, Wellsburg, W. Va.
Doyle, A. M., Canadian General Electric Company, Toronto, Ont., Canada.
Durbeck, E. F., Jr., Louisville Gas and Electric Company, Louisville, Ky.
Dyer, W. L., Southern California Edison Company, Ltd., Long Beach, Calif.
Enschede, M. H., Pacific Tel. & Tel. Co., Seattle, Washington.
Festner, R. H., New York Telephone Company, New York, N. Y.
Fulmer, J. L., Southern Bell Telephone and Telegraph Company, New Orleans, La.
Funderburg, C. H., Tennessee Valley Authority, Pickwick, Tenn.
Genthner, H. J., Rochester Gas and Electric Corporation, Rochester, N. Y.
Giba, J. J., Arma Engineering Company, Inc., Brooklyn, N. Y.
Giegerich, B. V., General Electric Company, Pittsfield, Mass.
Hagadorn, F. G., General Electric Company, San Francisco, Calif.
Hamilton, H. L., Keystone Pipe Line Company, Philadelphia, Pa.
Havens, M. LeR., 40 Arneys Mount Road, Pemberton, N. J.
Hellmann, R. K., Transatlantic Research and Information Service, Inc., New York, N. Y.
Hickey, W. J., Consolidated Edison Company of New York, Inc., New York, N. Y.
Hollifield, R., Ohio Edison Company, Akron.
Holt, C. B., Jr., Pennsylvania State College, State College, Pa.
Jewett, LeR. R., Gamewell Company, Sacramento, Calif.
Johnson, W. R., Tennessee Valley Authority, Chattanooga, Tenn.
Joyce, T., Union Electric Company of Missouri, St. Louis, Mo.
Kado, Y., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Koch, C. A., Cleveland Railway Company, Cleveland, Ohio.
Kyne, S. B., Connecticut Light and Power Company, Norwich.
Leitch, J. D. (Member), Electric Controller and Manufacturing Company, Cleveland, Ohio.
Lincoln, G. E., Western Union Telegraph Company, New York, N. Y.
Loehr, J. E., Consolidated Edison Company of New York, Inc., New York, N. Y.
Marshall, M. G., Commonwealth and Southern Corporation, New York, Jackson, Mich.
Masters, L., Eisemann Magneto Corporation, Brooklyn, N. Y.
McDonald, D. B., Texas Electric Service Co., Fort Worth, Texas.
McDonald, J. P., Scranton Electric Company, Harding, Pa.
McNamara, F. T., Yale University, New Haven, Conn.
Merwin, G. W., American Telephone and Telegraph Company, New York, N. Y.
Miller, M. C. (Member), Ebasco Services, Inc., New York, N. Y.
Neal, C. W., Oklahoma Gas and Electric Co., Oklahoma City, Okla.
Norberg, H. A., Phillips Petroleum Company, Bartlesville, Okla.

Owen, L. E., Tennessee Valley Authority, Wilson Dam, Ala.
Parks, W. K., Westinghouse Electric & Manufacturing Company, Buffalo, N. Y.
Peabody, A. W., Phoenix Engineering Corporation, New York, N. Y.
Pepperberg, L. E., Republic Steel Corporation, Cleveland, Ohio.
Peterson, J. A., Commonwealth and Southern Corporation, Jackson, Mich.
Putnam, T. R., New York Telephone Company, New York, N. Y.
Raab, C. F., Tennessee Valley Authority, Chattanooga, Tenn.
Rue, F. H., Norma-Hoffmann Bearings Corporation, Stamford, Conn.
Relfe, D. H., Port of Oakland, Oakland, Calif.
Rexroth, B. A., Southwestern Bell Telephone Company, Oklahoma City, Okla.
Rice, J. B., Allis-Chalmers Manufacturing Company, Pittsburgh, Pa.
Salisbury, A. M., Westfield Gas and Electric Department, Westfield, Mass.
Scheffer, S. L., Phoenix Engineering Corporation, New York, N. Y.
Shelton, S. P., Bureau of Power and Light, City of Los Angeles, Calif.
Sherry, R. P., Long Island Lighting Company, Glenwood Landing, N. Y.
Slater, E. A. (Member), Westinghouse Electric & Manufacturing Company, San Francisco, Calif.
Spencer, H. H., Bell Telephone Laboratories, Incorporated, New York, N. Y.
Stanley, W. McC., Tennessee Valley Authority, Wilson Dam, Ala.
Starr, F. C., General Electric Company, Rochester, N. Y.
Stein, G. M. L. (Member), General Electric Company, Pittsfield, Mass.
Stemler, D. R., Pennsylvania Power & Light Company, Allentown, Pa.
Toth, A., International Printing Ink Company, New York, N. Y.
Tratt, F. H., Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y.
Vallin, G. L., General Electric Company, Pittsfield, Mass.
Walsh, P. H., Jr., Paul H. Jaehnig, Inc., Newark, N. J.
Watkins, J. H., Jr., General Electric Company, Pittsfield, Mass.
Weaver, C. E., Eastman Kodak Company, Rochester, N. Y.
Woods, C. A., Jr., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Wright, N. G., Ohio Brass Company, Barberton, Ohio.
Wyatt, C. H., Oklahoma Gas & Electric Co., Oklahoma City, Okla.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute record. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Bodine, Ralph B., 14 N. Ferry, Schenectady, N. Y.
Boissonnault, F. L., 928 W. 8th Place, Los Angeles, Calif.
Charlton, H. C., 4827 Wilson Avenue, Montreal, Que., Canada.
Cooper, Peter G., 50 Stanton St., Schuykill Haven, Pa.
Dadashev, Musa, 32 Zamkovaja, Ulitsa, Baku, U.S.S.R.
Eakins, William V. G., 45 W. Mohawk St., Buffalo, N. Y.
Fassett, Frank C., 100 Seward Ave., Detroit, Mich.
Gregory, G. A., 1217 Jefferson Street, Olympia, Wash.
Hall, John R., 1464 S. 74th St., West Allis, Wis.
Herr, Melvin D., South 228 Lincoln St., Spokane, Wash.
Kirk, W. C., 216 E. 22nd St., Owensboro, Ky.
Koziol, Roman Joseph, 174 Farmington Ave., Hartford, Conn.
Macomber, George S., Federal Power Commission, Washington, D. C.
Matthews, Robert W., 42 St. Stephen St., Boston, Mass.
McLean, Lee Vance, 1926 North Blvd., Baton Rouge, La.
Rizk, Kaleel S., Co. 418, C.C.C., Olustee, Fla.
Roberts, William N., 4175 Springle, Detroit, Mich.
Tribble, William Harry, 303 Park Place, Brooklyn, N. Y.
Williams, Thomas J. C., 325 Seward Place, Schenectady, N. Y.

19 Addresses Wanted

# Engineering Literature

## New Books in the Societies Library

Among the new books received at the Engineering Societies Library, New York, recently are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface of the book in question.

MODERN ELECTRIC and GAS REFRIGERATION. By A. D. Althouse and C. H. Turnquist. Chicago, Goodheart-Willcox Company, 1936. 858 pages, illustrated, 8x5 in., leather, $5.00. A practical textbook for school use and home study.

PHYSICS of ELECTRON TUBES. By L. R. Koller. 2nd edition. New York and London, McGraw-Hill Book Company, 1937. 284 pages, illustrated, 9x6 in., cloth, $3.00. Considers the fundamental physical phenomena of electron tubes, disregarding external circuit conditions. The revision consists of corrections, added topics, and some expansion. Designed to interest technical men having no special training in electronics.

RECOLLECTIONS and REFLECTIONS. By J. J. Thomson. New York, Macmillan Company, 1937. 451 pages, illustrated, 10x6 in., cloth, $4.00. Mainly autobiographical, covering school and college days, first experimental work, visits to various countries, and psychical research. Later chapters contain sketches of contemporaries and lucid descriptions of certain important developments in the field of physics in which Thompson had a part, or which came within his time.

REPORTS on PROGRESS in PHYSICS, volume 3, edited by A. Ferguson. Published by the Physical Society, London, at University Press, Cambridge, 1937. 394 pages, illustrated, 10x7 in., cloth, 20s. Provides a review of the advances in physics during 1935. Among the subjects covered are: general physics, atomic physics, the measurement of noise, magnetism, experimental electricity and magnetism, electrical methods of counting, superconductivity, and the theory of metals, photoelectricity, optics, X rays, and spectroscopy.

SCIENCE MUSEUM. Board of Education. ELECTRIC ILLUMINATION, by W. T. O'Dea. London, His Majesty's Stationery Office, 1936. 40 pages, illustrated, 10x6 in., paper (obtainable from British Library of Information, 270 Madison Ave., New York, $0.20). A brief sketch of the principles, application, and development of electric lighting, prepared for general use by the Science Museum.

TROUBLES of ELECTRICAL EQUIPMENT. By H. E. Stafford. New York and London, McGraw-Hill Book Company, 1937. 330 pages, illustrated, 9x6 in., cloth, $3.00. A treatment of the ills of electrical equipment from the diagnostic viewpoint. For the practical man.

UNIFORM SYSTEM of ACCOUNTS for ELECTRIC UTILITIES. Edited by National Association of Railroad and Utilities Commissioners. New York, State Law Reporting Company, 1937. 213 pages, tables, 9x6 in., paper, $2.00. Prepared by the committee on statistics and accounts of public utilities, and recommended to the commissions represented in the membership of the Association at the 1936 convention.

WIRELESS SERVICING MANUAL. By W. T. Cocking. 2nd edition. London, Wireless World, Iliffe and Sons, 1936. 231 pages, illustrated, 5s. Devoted entirely to servicing problems; the reader is assumed to have a knowledge of basic principles.

APPLIED GEOPHYSICS, by H. Shaw. London, Science Museum. Publ. by His Majesty's Stationery Office, 1936. 102 p., illus., 10x6 in., paper, 2s. (Obtainable from British Library of Information, 270 Madison Ave., New York, $.65.) Intended as a guide to the exhibit of geophysical apparatus in the Science Museum, London; in addition contains an explanation of the various methods of geophysical surveying.

ELECTROLYTIC CONDENSERS. By P. R. Coursey. London, Chapman & Hall, 1937. 172 p. illus., 9x6 in., cloth, 10s. 6d. A summary of recent developments in the design of electrolytic condensers, together with an account of their properties and uses.

ELEKTROTECHNISCHE ISOLIERSTOFFE, Entwicklung, Gestaltung, Verwendung; Vorträge von H. Burmeister, W. Eitel, W. Estorff, W. Fischer, K. Franz, G. Pfestorf, R. Vieweg, W. Weicker. Ed. by R. Vieweg. Berlin, Julius Springer, 1937. 295 p., illus., 10x6 in., cloth, 19.80 rm. A series of lectures which aimed to give a review of the present development of insulating materials, both scientifically and technically.

INTRODUCTION to FERROMAGNETISM. By F. Bitter. New York and London, McGraw-Hill Book Co., 1937. 314 p., illus., 9x6 in., cloth, $4.00. Defines the problems whose solution may be expected to reveal the fundamental processes which constitute ferromagnetism, and discusses magnetic, mechanical, and electrical phenomena.

ORIGINS of CLERK MAXWELL'S ELECTRIC IDEAS as described in familiar letters to William Thomson. Ed. by Sir Joseph Larmor. Cambridge (England) The University Press; New York, Macmillan Co., 1937. 56 p., illus., 10x7 in., cloth, $1.00. Contains a series of letters written between 1854 and 1879 that present an account of the genesis and rapid progress of Maxwell's ideas.

THEORY of ALTERNATING-CURRENT MACHINERY. By A. S. Langsdorf. New York and London, McGraw-Hill Book Co., 1937. 788 p., illus., 9x6 in., cloth, $6.00. A text for advanced electrical engineering students, giving a comprehensive discussion of all types of electromagnetic machines as well as of the basic principles which influence their design and operating characteristics; quantitative relations are approached through the medium of geometrical representation.

VERSUCHE zur ELEKTRISCHEN RESONANZ mit HOCHFREQUENTEN und NIEDERFREQUENTEN WECHSELSTRÖMEN (Versuche mit kleinen Röhrengeneratoren). (Abhandlungen zur Didaktik und Philosophie der Naturwissenschaft, Heft 16). By F. Moeller. Berlin, Julius Springer, 1937, 1937. 82 p., illus., 11x8 in., paper, 4.80 rm. A guide to numerous experiments in the field of resonance with small vacuum-tube generators.

VORSCHRIFTENBUCH des VERBANDES DEUTSCHER ELEKTROTECHNIKER. Ed. by die Geschäftsstelle des VDE. 21 ed. Berlin, Verband Deutscher Elektrotechniker, 1937. 1414 p., illus., 8x6 in., cloth, 16.20 rm. Contains a complete set of the specifications, rules, and practices for electrical work adopted by the Society of German Electrical Engineers and in force on January 1, 1937.

WHO'S WHO in ENGINEERING, a Biographical Dictionary of the Engineering Profession. Ed. 4, 1937. Ed. by W. S. Downs. New York, Lewis Historical Publishing Co., 1937. 1638 p., 10x6 in., cloth, $10.00. Contains brief professional biographies of 12,000 American engineers.

**Engineering Societies Library**
29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a co-operative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**Federal Power Commission Hearing.**—The Federal Power Commission will hold a public hearing on November 15, in Washington, D. C., on the application of the Pacific Gas & Electric Co., San Francisco, for a preliminary permit to construct six major hydroelectric developments on the North Fork of the Feather River, having an aggregate proposed installed capacity of 368,000 kva. The company at present owns and operates the only three hydroelectric plants on the North Fork of the Feather River. These are known as Big Bend, Bucks Creek, and Caribou plants. The six proposed plants are planned to be built between the Caribou plant and the Big Bend plant. The difference in elevation between these two points is 2,072 feet and it is this difference in elevation or head of the river which is to be developed through the proposed construction. On the date of the application, the company is shown as operating 39 hydroelectric plants, two operated under lease, with a total installed capacity of 1,011,285 horsepower and 8 steam plants with a total installed capacity of 426,608 horsepower.

**Westinghouse Expands Elevator Plant.**—One of the largest and most complete elevator and electric stairway plants in the world is now located in Jersey City, as a consequence of the recent acquisition by the Westinghouse Elevator Co. of the assets of the A. B. See Elevator Co., Inc. With the removal of the Westinghouse company's headquarters from Chicago to Jersey City, plans have gone forward for increasing the manufacturing aisle space at the plant at 150 Pacific Ave., Jersey City, by approximately 50 per cent, and for doubling office space there. The A. B. See Company, third largest in the industry, was founded in 1883 by Alonzo Bertram See, and specialized in apartment house and industrial elevators.

**General Electric Orders Rise.**—Orders received by the General Electric Co., during the first nine months of this year amounted to $305,276,556, an increase of 44 per cent over the $211,891,038 received during the same time last year. Sales billed during this period amounted to $260,773,533 compared to $189,263,156 during the corresponding period of 1936, an increase of 38 per cent. Orders received during the third quarter this year amounted to $88,010,937 compared with $74,922,441 during the corresponding period last year, an increase of 17 per cent. The third quarter and the first nine months during 1937 were the largest of any similar periods since 1929.

**Roller-Smith Appointment.**—C. F. Cate, 234 N. Davis St., El Paso, Texas, has been appointed sales agent for the Roller-Smith Co., of New York City, for the southwestern portion of Texas and the southern portion of New Mexico.

**U. S. Rubber Appointment.**—The mechanical goods division of U. S. Rubber Products, Inc., has announced the appointment of Frederick D. Benz, formerly manager of wire sales, Chicago branch, as district manager of wire sales, Pacific division, with headquarters at San Francisco.

**Cutler-Hammer Appointments.**—A. R. Johnson has been appointed manager of the merchandising sales division of Cutler-Hammer, Inc., Milwaukee; Elmer F. Weiss is now manager of the Detroit office, succeeding Mr. Johnson; E. T. Rees has been appointed branch sales manager of the office in Indianapolis, and a new branch sales office at Portland, Oregon, has been opened with F. J. Woldrich in charge.

**New Thread-Cutting Screw.**—The Shakeproof Lock Washer Co., 2501 N. Keeler Ave., Chicago, Ill., has announced the development of a screw that cuts its own thread in metals and plastics of practically any thickness. Its patented, thread-cutting slot, plus a special hardening process, eliminates the separate tapping operation normally required in the use of standard machine screws. Important production savings in both labor costs and time are claimed for use of this new fastening method.

**Improved Solenoid Relay.**—An improved Durakool mercury switch is now used on type A solenoid relays manufactured by G-M Laboratories, Inc., Chicago. The Durakool switch is of unbreakable construction; the steel shell enclosing the chamber contains mercury and a liquid fill. The liquid fill is a new development which insures maximum initial contact, prevents oxidation, quenches the arc and washes away impurities. The steel enclosure is covered with a Bakelite housing. This type relay has proved particularly suited to operations where an enclosed switch contact is desirable or necessary, such as a refrigerator fan control.

# Trade Literature

**Millivoltmeters.**—Bulletin 480. Describes recording millivoltmeters for electrolysis surveys. Scales and ranges are included. The Bristol Co., Waterbury, Conn.

**Oscillograph.**—Bulletin, 4 pp. Describes new, type 168, Du Mont all purpose 5-inch cathode-ray oscillograph. Portable, for laboratory or field. Allen B. Du Mont Laboratories, Inc., Upper Montclair, N. J.

**Industrial Lighting Equipment.**—"Handbook of Localized Lighting," ML6, 16 pp. Describes flexible arm lighting units with various types of reflectors, including indirect canopy types. The Fostoria Pressed Steel Corp., Fostoria, O.

**Transformers.**—Bulletin (broadside). Illustrates 14 of the various types of transformers of this manufacturer, principally distribution and power equipment. R. E. Uptegraff Manufacturing Co., 300 N. Lexington Ave., Pittsburgh, Pa.

**Tree Wire.**—Bulletin C-36, 8 pp. Describes Anaconda Duracord tree wire. Includes interesting illustrated tests indicating the reliability of such wires under extreme operating conditions. Insulation thickness tables are also included. Anaconda Wire & Cable Co., 25 Broadway, New York City.

**Pin Type Insulators.**—Bulletin 39-1918, 4 pp. Describes radio interference proof, high voltage, pin type insulators—the method of applying copper oxide glaze, application of insulators, and methods of testing for radio interference. Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

**Stiffness Testers.**—Bulletin 11, 12 pp. Describes various types of machines for testing stiffness of practically all materials, in every form, as well as many manufactured products used in industry. Methods of tests are outlined in full, and diagrams showing results of typical tests are included. Tinius Olsen Testing Machine Co., 500 N. 12th St., Philadelphia, Pa.

**Radio Noise Suppression.**—Folder, "Clear Reception," on the subject of background noise suppression. The several ways in which noises reach a receiver and how they may be stopped either at the set itself, or preferably at the noise source, are outlined. Also featured are the several types of noise eliminators or filters. Aerovox Corp., 70 Washington St., Brooklyn, N. Y.

**Conduit, Insulating Materials, Etc.**—Catalog G1-6A, 64 pp. Includes chapters on asbestos-cement conduit for electrical wires and cables; Asbestos Ebony, used for switchboard panels and other electrical mountings; Transcell for cell structures and doors. Among other products described are built-up and insulated roofs, industrial friction materials, pipe insulations, packings, gaskets, etc. Johns-Manville, 22 E. 40th St., New York City.

**Non-Metallic Underground Cable.**—Bulletin UC-2, 16 pp. Describes Trenchlay and Ruralay cables for direct earth installation on single phase systems. Summarizes the economic and other advantages of these types of cables for rural application, and illustrates installation and splicing methods. A comparative voltage drop chart for a specific overhead and underground line is included in the bulletin. General Cable Corp., 420 Lexington Ave., New York City.

**New Photoelectric Potentiometer.**—Bulletin 501-A, 4 pp. Describes Model 721 photoelectric potentiometer and its related equipment. The unique electronic balancing method of the new instrument is outlined, whereby widened application of potentiometric sensitivity to continuous measurement and control of rapidly varying electrical quantities, or other quantities (temperature, light, etc.) may be translated into electrical units. Among the fields of application for the unit, suggested in the bulletin, are pyrometry, electrochemical measurement and control, standardization and regulation of currents, voltages, light values, etc. Weston Electrical Instrument Corp., Newark, N. J.

**Earnings of Engineers.** Statistics based upon monthly earnings of engineers suggest conclusions different from those deduced by an analysis of the annual earnings. A continuation of a comprehensive survey of employment in the engineering profession shows marked differences in earnings within each professional class, and within each group classified on the basis of educational background (*pages 1450–60*).

**Winter Convention.** An enlarged program will feature the AIEE 1938 winter convention to be held January 24–28 in New York, N. Y. Tentatively, 66 papers have been scheduled to be discussed in 16 technical sessions. The program will include also several addresses and technical conferences, and a post-convention cruise to Bermuda (*pages 1516–17*).

**Co-operation Among Societies.** Two years of successful operation attest to the effectiveness of the co-operative action that resulted in the organization of the Technical and Scientific Societies Council of Cincinnati, Ohio, which brings together ten organizations comprising some 1,500 members (*pages 1525–6*).

**Trolley-Coach Operation.** The so-called "trackless trolley" has been adopted for public transportation in more than 30 cities in the United States, and in Europe. Some operating experiences with trackless trolleys on systems situated on opposite sides of the United States have been summarized and are presented in two papers in this issue (*pages 1461–3 and 1483–6*).

**Oil Oxidation.** Separate studies of the effect of equal amounts of air and of nitrogen in cable paper impregnated with oil, of the oxidation behavior of the oil alone and as affected by paper and metal, produce new information regarding the progressive changes of electrical characteristics of oil-impregnated cables (*pages 1492–1501*).

**American Engineering Council.** Recommendations for a public works department, and discussions of mapping by government agencies and of scientific research legislation now under consideration by Congress were included in the current "News Letter" of American Engineering Council (*pages 1526–7*).

**The Dielectric Circuit.** Electrostatics and the theory of the dielectric circuit frequently are confusing to students of electrical engineering. A teacher, who is renowned among his own students for his ability to make abstruse subjects lucid, has presented the fundamentals of dielectric-circuit theory in graphic style (*pages 1454–40*).

**Institute Directors Meet.** At the October 28 meeting of the AIEE board of directors, the budget for the year 1937–38 was adopted, representatives on joint organizations and committees were appointed, a revised publication policy was adopted, and other questions of importance to the membership discussed (*page 1518*).

**1937 Index . . . . . 1537**

On the 20 pages beginning with page 1537 of this issue is published the annual reference index, listing some 2,200 entries, covering all text material published in ELECTRICAL ENGINEERING during 1937. Special information regarding the index is given on page 1537.

**Insulation Committee Meets.** The tenth annual meeting of the committee on electrical insulation of National Research Council was characterized by the usual spontaneous and informal discussion, and reflected the continuing advance of research in dielectrics (*pages 1520–2*).

**United Engineering Trustees.** Officers were elected and annual reports presented at the annual meetings of United Engineering Trustees, Inc., and the Engineering Foundation; the annual report of the Engineering Societies' Library also was presented (*pages 1527–30*).

**Stray-Load Losses.** A method of measuring the stray-load losses of d-c machines, which is described in a paper in this issue, is adaptable to the testing departments of manufacturers, and requires no special equipment (*pages 1487–91*).

**Switching Surges.** The magnitude and characteristics of abnormal voltage transients accompanying operation of load-ratio control cotractors on power transformers have been studied both experimentally and theoretically (*pages 1464–75*).

**Telephone Research.** Transmitters and receivers have been developed to their present high quality by research which includes an extensive analysis of the composition of speech sounds and the study of hearing (*pages 1441–8*).

**Exposition Lighting.** Plans for the illumination of the Golden Gate Exposition in 1939 reveal the large part that lighting will play in novel forms at this $50,000,000 fair (*page 1449*).

**Institute Budget.** The AIEE budget, as adopted by the board of directors for the year 1937–38, provides for a broadening of several essential services to the membership (*pages 1433; 1522–4*).

**Noble Prize Awarded.** For the third time since its establishment in 1931, the Alfred Noble prize has been awarded to an AIEE member (*page 1519*).

**Multiple Unbalances.** The solution of a network containing a multiple unbalance may be simplified by the use of a network analyzer (*pages 1476–82*).

**Letters to the Editor.** A rotor-flux-locus concept of single-phase induction-motor operation is discussed in this month's "Letters" section (*page 1531*).

**New AIEE Section.** The Institute's 64th Section recently was organized at Tulsa, Okla. (*page 1518*).

# DISCUSSIONS

Appearing in this issue are discussions of the following papers:

## Electrical Machinery

The Saturated Synchronous Machine—Robertson, Rogers, and Dalziel 1502

## Electric Ranges

Heat Transfer Efficiency of Range Units—Walsh . 1512

## Protective Devices

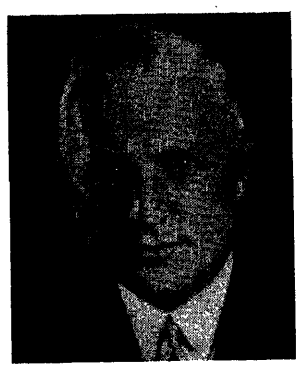
Surge Protection of Distribution Systems—Hodnette and Ludwig 1503
Distribution Lightning Arrester Performance Data—Subcommittee Report 1507
Expulsion Protective Gaps—Rudge and Wade . . 1508
Flashover Characteristics of Rod Gaps and Insulators—EEI-NEMA Joint Committee Report 1510
Relay Operation During System Oscillations—Mason 1513
Capacitance Control of Voltage Distribution in Multibreak Breakers—Van Sickle 1514
The Ultrahigh-Speed Reclosing Expulsion Oil Circuit Breaker—Schwager 1514
A Comprehensive Method of Determining the Performance of Distance Relays—Neher 1515

## Transmission and Distribution

Lightning Currents in 132-Kv Lines—Sporn and Gross 1511
Probable Outages of Shielded Transmission Lines—Waldorf 1511

Statements and opinions given in articles and papers appearing in ELECTRICAL ENGINEERING are the expressions of contributors, for which the Institute assumes no responsibility. Correspondence is invited on all controversial matters. ¶ Subscriptions—$12 per year to United States, Mexico, Cuba, Porto Rico, Hawaii, Philippine Islands, Central and South America, Haiti, Spain, Spanish Colonies; $13 to Canada; $14 elsewhere. Single copy $1.50. ¶ Address changes must be received by the fifteenth of the month to be effective with the succeeding issue. Copies undelivered because of incorrect address cannot be replaced without charge. ¶ ELECTRICAL ENGINEERING is indexed annually by the Institute, weekly and monthly by *Engineering Index*, and monthly by *Industrial Arts Index*; abstracted monthly by *Science Abstracts* (London).

¶ Copyright 1937 by the American Institute of Electrical Engineers.



Number of copies this issue—21,800.

# The AIEE 1937-38 Budget

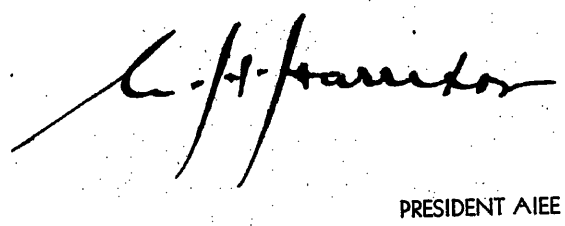
## *To the Membership:*

AT ITS MEETING on October 28 your board of directors adopted the budget for the year ending September 30, 1938, the details of which are covered on pages 1522–4. There are some phases of the board's consideration of the budget which seem of special interest.

The broad operations of the Institute have been conducted in an excellent manner and the modest surplus accumulated over a period of years shows an encouraging trend—a commendable showing especially as the essential services to the membership have been maintained at a satisfactory level. A few years back, here and there some curtailment of expenditures was necessary; but through constructive co-operation and sympathetic understanding of the membership at large, interest in the affairs of the Institute was sustained and activities broadened, even during these years.

President Harrison

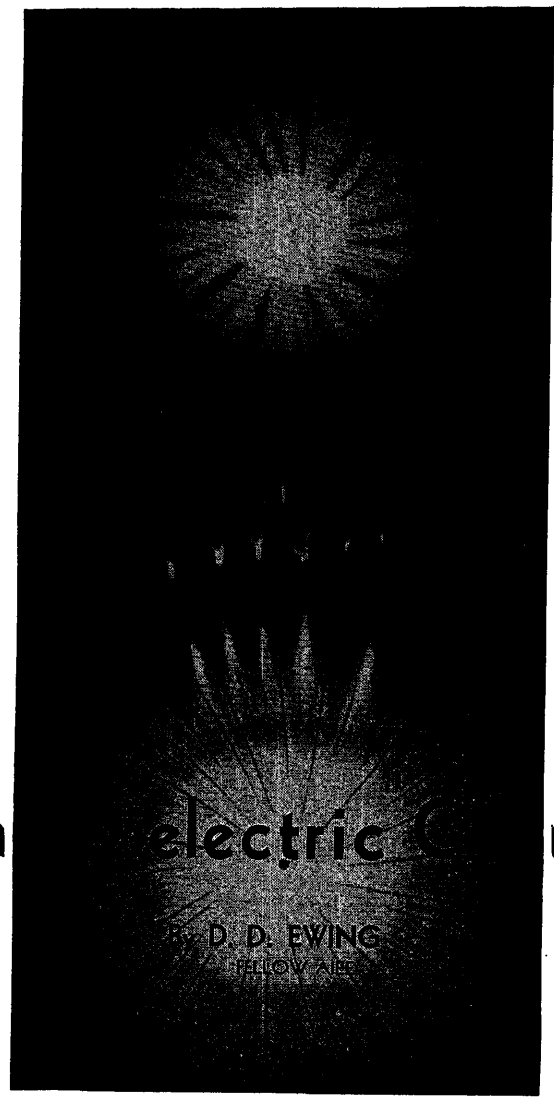
The budget for the current year assumes that revenues will increase $10,000 as contrasted with last year and that expenditures will increase $30,000 over the same period. Total revenues are expected to be $299,500 and expenses $299,000—practically nothing to be carried over to surplus.



Some in the membership may question the wisdom at this time of planning expenditures on such a liberal basis and so close to the estimated income. The board recognized this but thought it proper, all things considered, to broaden several of the essential services. With the interest of the membership so great, and with so much voluntary effort being expended in behalf of the work of the Institute, it seemed clear that increased appropriations for some activities would produce substantial benefits.

In considering the expenditures it will be realized how well they are directed toward the fulfillment of the two objectives for which the Institute was created and exists: ". . . the advancement of the theory and practice of electrical engineering and of the allied arts and sciences and the maintenance of a high professional standard among its members." A considerable part of our activity centers about our publications and meetings. These activities not only satisfy the first objective but, in addition, the free interchange of information and the personal contacts which they provide are an important contribution toward the second objective. More money will be spent this year than last on publications and on national, District, Section, and Branch meetings. It is interesting to note that what we pay for is the machinery by means of which we receive a continuous flow of invaluable information and, in turn, impart to our fellow members information of value which we possess. We pay nothing for the information—we pay only for the paper, the printing, the meeting places, and the other means through which we obtain and discuss the information conveniently. A new publication policy which is to be put into practice next month and which is expected to make the publications of even greater value, already has been described in the November issue of ELECTRICAL ENGINEERING.

The Institute's objectives are also advanced through the contributions made for the support of the American Engineering Council, the Engineers' Council for Professional Development, the American Standards Association, the Engineering Societies' Library, and similar organizations through which the Institute co-operates with other national engineering societies in considering and acting on matters of common concern to the engineering and allied technical professions.



Every member of the Institute will get something of value from the sum total of expenditure no matter where he may be located. However, it is those who actively take part in the Branch, Section, and other Institute affairs who will get the greatest value. Let each of us read the publications, go more often to meetings, enter more actively into the discussions of talks and papers, and participate in the business of the committees to which we may belong. We will find that there is hardly an activity of any kind within the scope of the professional interests of an electrical engineer in which the Institute is not engaged through its committees and relations with other bodies.

We have undertaken an ambitious budget of expenditures. Your board is mindful too that still further expenditures could be made to advantage. Our principal source of income is from members in the form of dues. To assure the carrying out of this year's program and to make possible an ever broadening range of desirable activities, an increase in membership rolls is essential. Consideration of the budget makes this evident. I earnestly ask your continuing support toward this end.

PRESIDENT AIEE

# The Dielectric Circuit

**The dielectric circuit is a baffling enigma to many undergraduate students of electrical engineering; indeed, to many engineers whose work is not intimately concerned with it. This outline of some of the elementary notions regarding electrostatics and the dielectric circuit is presented here because of its possible interest and value to students and others wishing to review the subject with the aim of attaining a working knowledge of it.**

THERE IS AN ancient proverb that says in part: "he who is first shall be last." This phrase seems to have some application to the subject of electrostatics. Until Galvani and Volta made the discoveries that "galvanized" the subject of electrodynamics into life, at about the same time the present form of constitutional government was being born in the United States, the world's knowledge of electricity, and its effects, was confined pretty much to the subject of electrostatics. The versatile and questioning Franklin made many forays into this field of thought and his feat of flying a kite during a thunderstorm is known to every school boy. But with the discovery of the voltaic cell in the passing days of the eighteenth century came the great developments in the field of electrodynamics, which for a century completely overshadowed almost everything pertaining to the subject of electrostatics. True, lightning remained as a manifestation of natural electrostatic activity, and some use was found for capacitors and similar electrostatic apparatus, but a general interest in electrostatics and the dielectric circuit was quickened only when such interest was demanded by the more complex problems in telephony and radio, and by the insulation and other electrostatic problems associated with high-voltage apparatus.

Few indeed were the electrical-engineering curricula that contained any but the most meager courses of instruction in electrostatics 25 years ago; but today this neglect is not so general. As students in physics and in beginning courses in electrical engineering most of the readers of this article devoted some little time to studies of the dielectric circuit. Unfortunately it seems to be a subject about which the average seniors in electrical engineering—yes, even most of the engineers engaged in the ordinary routine work of the electrical engineer—have almost unlimited powers of forgetfulness. In the hope of paving the way, as it were, for a flying start in further studies of transmission lines and problems concerning high voltages this brief review of some of the elements of electrostatics and the dielectric circuit has been prepared.

In the space available it is not possible to give credit to all those deserving it. Also, from a strictly rigorous point of view, some readers may wish to question the methods and the accuracy of some of the illustrations used in this review. Be that as it may, the immediate object is to arrive at a reasonable working knowledge of the dielectric circuit, and the finer distinctions may well be left for argument at some other time.

For convenience, and for the purpose of securing a bird's eye view of the realm of electrostatics, the accompanying "tabloid" presentation of the subject has been arranged.

As a foundation for this discussion, almost all knowledge of the dielectric circuit may be said to be based upon the 5 fundamental laws contained in the first "box" of the tabloid presentation. Now these "laws," as most readers well know, are not written on the statute books of this or any other country. They are compilations of bits of fundamental truth refined from the elementary discoveries of many investigators. They are all based on knowledge experimentally determined. Whether or not they may be determined by rational processes instead of experimentation is a subject that is left to the physicists. For the present these laws will be considered "constitutional," at least until thrown aside by the high court of rigorous scientific research.

---

Written especially for ELECTRICAL ENGINEERING, this article presents the essence of a review lecture delivered by the author to a group of senior electrical-engineering students at Purdue University.

D. D. EWING is professor of electrical engineering at Purdue University, Lafayette, Ind. A native (1883) of Vanlue, Ohio, he was graduated in electrical and mechanical engineering from Ohio Northern University in 1906, following which he spent a year in telephone and railway work. In 1907 he was appointed to the faculty of Ohio Northern University as professor of electrical and mechanical engineering, and remained in that position until 1913, when he became assistant professor of electrical engineering at Purdue University. Subsequently he became associate professor, and received his full professorship in 1918. Besides his regular teaching duties, Professor Ewing has devoted much time to consulting engineering work. He is co-author of a textbook and author of many papers on electric railway engineering. He has been a member of the Institute's committee on electric welding since 1932, and is a member of the committees on power transmission and distribution, and transportation.

These basic principles are, or should be, well known to everyone who has studied even an elementary course in physics. Misunderstanding comes when one desires to make use of this basic knowledge in the solution of the practical problems with which the engineer is familiar as part of his daily routine of duties.

The first law, namely, the law of electrostatic attraction, or repulsion, has been known for many years. The language and symbolism used in describing this law are, of course, recent; but the basic idea has been known for ages. Probably some cave-man ancestor of ours discovered it on a frosty day long ago when he stroked the back of some member of the cat family, which he was trying to tame. Thales, the Greek, wrote of the effect of rubbing amber in 600 B.C. and possibly others had noticed the effect and even written about it long before the time of Thales.

Coulomb, a contemporary of Washington and Franklin, making use of the first law, discovered the second law, which bears his name. The third law is not as well known as Oersted's discovery of a similar principle in electromagnetics but is just as true. Many readers have witnessed its demonstration—the usual procedure being to energize at high voltage a wire projecting upward through a horizontal pane of glass. Mica chips or bits of cotton lint scattered over the glass promptly arrange themselves in radial lines as shown in figure 1. The arrowheads in these figures indicate the direction of force action.

That the forces of electrostatic attraction, or repulsion, are greater in some media than in others was known to several of the earlier investigators in electrical science. In some dielectrics a given charge of electricity may produce from one to 10 times the force action that is produced in air (see the fourth law).

Like the law of attraction, or repulsion, the law of electrostatic induction (fifth law) has been known, in effect at least, for many years. Its scientific observation and formulation, however, belong to a more recent date. Other laws and effects of importance might be enumerated, but at the moment and for the present purpose, the groups of discoveries formulated in the "box" of basic laws seem most important. From these experimental laws several concepts and definitions have been set up by the physicists. These are necessary in order that the engineer may be able to formulate his problems in electrostatics. By way of illustration the basic laws might be likened to the primary roots of a great tree as shown in figure 2. Growing out of these roots comes the "trunk" of definitions and concepts, and out of the trunk grow the ideas and formulas needed in the specific fields of practical application. The most useful of these concepts are placed in the second "box."

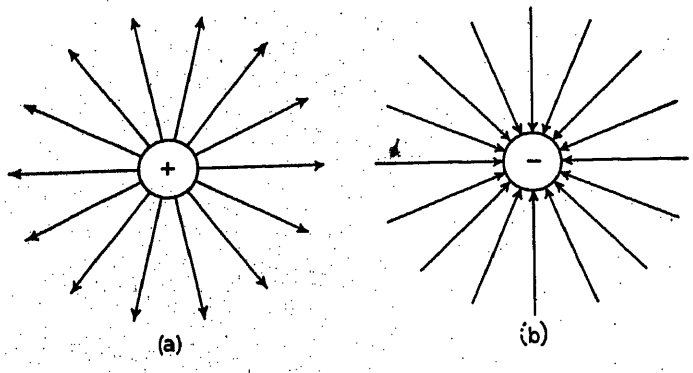


**Figure 1. Sketch of the dielectric flux lines around conductors carrying current**

(*a*)—Electrically positive conductor
(*b*)—Electrically negative conductor

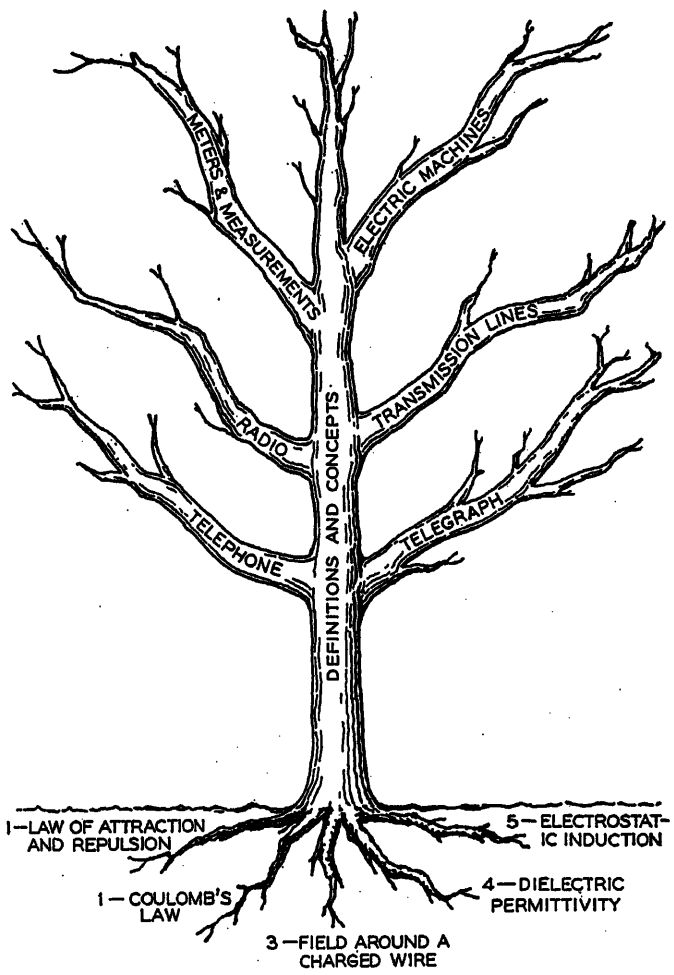

**Figure 2. The "tree" of dielectric laws and concepts**

The unit-charge concept comes directly from the first 2 laws, a unit charge of electricity being assumed to be of such magnitude that 2 similar unit charges placed one centimeter apart would repel each other with a force of one dyne. Here everything, it will be noted, is on a "unit" basis.

In order to determine the "strength" $g$ of a given field at a specified point, someone had the happy thought of placing a unit charge at that point and measuring the resulting force action. This concept of *field intensity* is based on the second law and is most useful in the formulation of problems, although no one ever attempts in a practical way to measure a unit charge, place it in an electrostatic field, and then with some sort of spring scale or balance measure the resulting force action.

# Electrostatics and the Dielectric Circuit

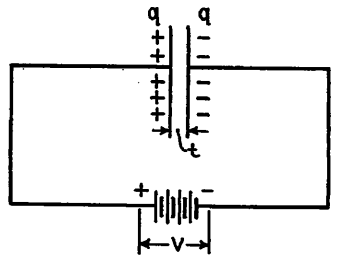
## 5 Basic Laws

1. Unlike charges attract; like charges repel.
2. The force of attraction (or repulsion) varies directly as the product of the charges and inversely as the square of the distance between them (Coulomb's Law: $F = q_1q_2/r^2$).
3. A charged wire is surrounded by an electrostatic field.
4. Some substances are more susceptible to electrostatic forces than are others.
5. A conducting body placed in an electrostatic field undergoes a change in potential (law of electrostatic induction).

## Definitions and Concepts

1. Unit charge.
2. Field intensity: $g = \frac{q \times 1}{r^2} = \frac{q}{r^2}$
3. Line of flux.
4. Flux per unit charge $= 4\pi$ lines

## Physicist



**Tools**

$g = D/K$ $\quad g = \frac{dE}{dr}$ or $\frac{dV}{dr}$

$q = VC$ $\quad D = \Psi/A$ $\quad \Psi = 4\pi q$

EXAMPLE 1—PLATE CAPACITOR

$A$ = total area of one plate
$t$ = thickness of dielectric

Assume $q$ units of charge on each plate; then $D = 4\pi q$, but $g = D/K = 4\pi q/KA$. Also $V = gt$ (see eighth concept); therefore, $g = V/t$ and

$$\frac{V}{t} = \frac{4\pi q}{KA} \quad \text{or} \quad V = \frac{4\pi qt}{KA}$$

But $V = q/C$ and $C = q/V$; therefore,

$$C = \frac{KA}{4\pi t} \text{ statfarads}$$

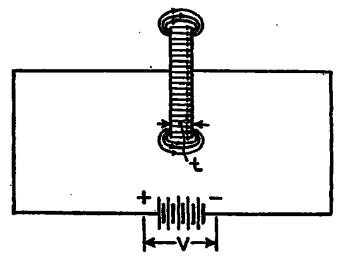
EXAMPLE 2—FIELD AROUND A CONDUCTOR

This method may be used for computing the potential difference between 2 concentric surfaces of radii $r_1$ and $r_2$ about the conductor. Let $q$ be the charge per centimeter of length of conductor. Then $\Psi = 4\pi q$ (fifth concept). At a radius of $x$ centimeters

$D = \frac{4\pi q}{2\pi x}$ (sixth concept); then $D = 2q/x$.

But $g = D/K$; therefore,

$$V_{r_2-r_1} = \int_{r_1}^{r_1} g\,dx = \int_{r_1}^{r_2} \frac{2q\,dx}{xK}$$



## Engineer

**Tools**

$\Psi = V/S$ or $E/S$ $\quad S = l/KA$ $\quad C = \frac{1}{4\pi S}$

EXAMPLE 1—PLATE CAPACITOR

$A$ = total area of one plate
$t$ = thickness of dielectric

First determine the elastance. This can be written at once, as

$$S = \frac{l}{KA} \text{ and } C = \frac{1}{4\pi S}$$

therefore

$$S = \frac{t}{KA}$$

because $t$ is the length of flux path, and

$$C = \frac{1}{4\pi \frac{t}{KA}} = \frac{KA}{4\pi t} \text{ statfarads}$$

EXAMPLE 2—FIELD AROUND A CONDUCTOR

This method may be used for computing the potential difference between 2 concentric surfaces of radii $r_1$ and $r_2$ about the conductor.

If $S = l/KA$, in this case $dS$ is

$dS = \frac{dx}{2\pi Kx}$ per centimeter length of conductor.

$$S = r_2 - r_1 \int_{r_1}^{r_2} dS = \int_{r_1}^{r_2} \frac{dx}{2\pi Kx} = \frac{1}{2\pi K} \log_e \frac{r_2}{r_1}$$

5. Dielectric flux per charge: $q = 4\pi q = \Psi$

6. Flux density: $D = Kg$; $D = \frac{\Psi}{A}$

7. Electrostatic potential:

$$E = \int_r^\infty g\,dr$$

where $g = f(r)$; that is, if $= g\,q/r^2$, then

$$E = \int_r^\infty \frac{q}{r^2}\,dr = \frac{q}{r}$$

8. Voltage = difference of potential $= V = \int_{r_1}^{r_2} g\,dr$

and $g = \frac{dV}{dr}$ or $dV = g\,dr$

For a flux path of uniform area $V = gl$, where $l$ = length of path. Since $V = gl$ and $g = D/K$,

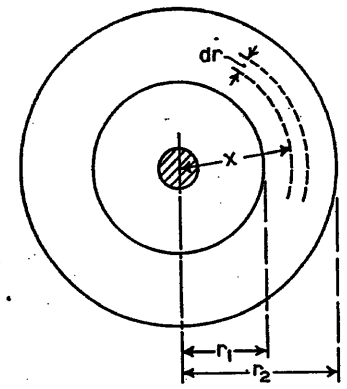
$$V = \frac{Dl}{K} = \frac{ADl}{KA}$$

therefore

$$V = \Psi\frac{l}{KA} = \Psi S$$

where $S = \frac{l}{KA}$

$$\frac{V}{S} = \Psi$$



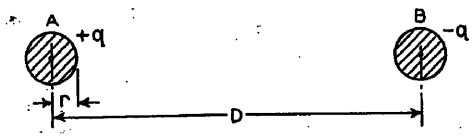
9. Unit capacitance: $V = q/C$; $C = q/V$; $q = VC$, where $V$ is the voltage impressed on capacitance $C$. Since $\Psi = 4\pi q$, $\Psi = 4\pi CE$ or $4\pi CV$; therefore,

$$\frac{V}{S} = 4\pi CV \quad \text{or} \quad S = \frac{1}{4\pi C}$$

and

$$C = \frac{1}{4\pi S}$$

where $C$ is the capacitance in farads



Integrating,

$$V_{r_2-r_1} = \frac{2q}{K}\log_e\frac{r_2}{r_1}\ \text{statvolts}$$

which is the voltage between the 2 surfaces.

EXAMPLE 3—LINE-TO-NEUTRAL CAPACITANCE IN A SINGLE-PHASE CIRCUIT

$V_{AB}$ = voltage between lines. Using the relations from the 2 previous examples,

$$V_{AB} = \int_r^D 2q\frac{dx}{x} - \int_r^D -2q\frac{dx}{x} = 4q\log_e(D/r)$$

remembering that in air $K = 1$. But

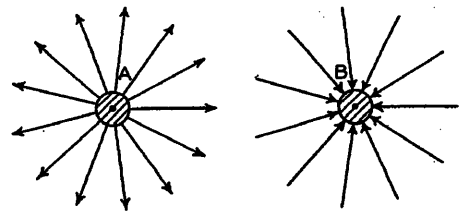
$$C = \frac{q}{V} = \frac{q}{4q\log_e(D/r)} \quad \frac{1}{4\log_e\frac{D}{r}}\ \text{statfarads}$$

which is the line-to-line capacitance. Since the line-to-neutral capacitance is twice the line-to-line capacitance, the line-to-neutral capacitance is

$$C_A = \frac{1}{2\log_e(D/r)}$$

statfarads per centimeter of length of the conductor.

But $V = \Psi S$; therefore (eight concept),



$$V_{r_2-r_1} = \frac{\Psi}{2\pi K}\log_e\frac{r_2}{r_1}$$

Since $\Psi = 4\pi q$,

$$V_{r_2-r_1} = \frac{4\pi q}{2\pi K}\log_e\frac{r_2}{r_1} = \frac{2q}{K}\log_e\frac{r_2}{r_1}\ \text{statvolt}$$

which is the voltage between the 2 conductors.

EXAMPLE 3—LINE-TO-NEUTRAL CAPACITANCE IN A SINGLE-PHASE CIRCUIT

Let $r$ = radius of conductor. Using the relations for the 2 previous examples,

$$V_{r_2-r_1} = \frac{\Psi}{2\pi K}\log_e\frac{r_2}{r_1}$$

Then the absolute potential of conductor $A$ is (that is, when $r_2 = \infty$ and $r_1 = r$, $V_{r_2-r_1}$ becomes equal to this value)

$$E_A = \frac{\Psi_A}{2\pi}\log_e\frac{\infty}{r} + \frac{\Psi_B}{2\pi}\log_e\frac{\infty}{D}$$

But $\Psi_A + \Psi_B = 0$ and also $\Psi_A\log_e\infty + \Psi_B\log_e\infty = 0$; therefore

$$E_A = \frac{\Psi}{2\pi}\left(\log_e\frac{1}{r} - \log_e\frac{1}{D}\right) = \frac{\Psi}{2\pi}\log_e\frac{D}{r}$$

But $E_A = \Psi S_A$; therefore,

$$\frac{1}{2\pi}\log_e(D/r) = S_A$$

$$C_A = \frac{1}{4\pi S_A} = \frac{1}{2\log_e(D/r)}\ \text{statfarads}$$

the line-to-neutral capacitance per centimeter length of conductor. $E_A$ is the absolute potential of conductor $A$ (line-to-neutral volts), and $S_A$ is the line-to-neutral elastance.

Whatever the invisible and mysterious thing is that surrounds a charged wire produces force action on electric charges. To assist in the visualization of this phenomenon Faraday's concept of lines of flux may be used, drawing a line per square centimeter for each dyne of force action (third concept). Since at any point distant one centimeter from a unit charge concentrated in a point the force is one dyne, and since a sphere of unit radius has an area of $4\pi$ square centimeters, it follows that the field around a unit charge may be represented by $4\pi$

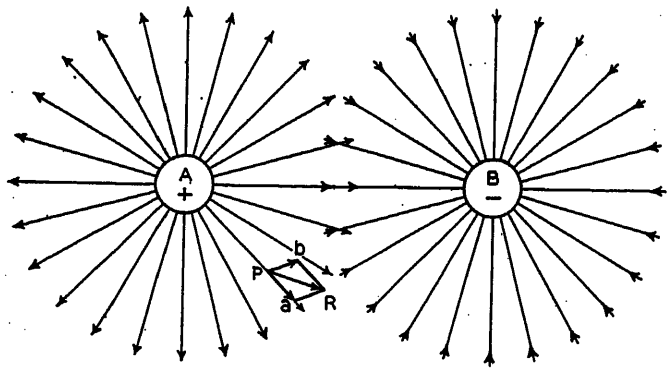


**Figure 3. Sketch of the component fields surrounding the conductors of a single-phase circuit**

lines of flux, the lines radiating from the charge like the spines of a sand bur (concept number 4). If, instead of a unit charge, the charge be of $q$ units, the total flux will be $4\pi q$ lines and the flux density (concept number 6) will be the total flux $\Psi$ divided by the area, or $D = \Psi/A$ lines per square centimeter. $D$, it will be noted from the previous discussion is equal numerically to the number of dynes of force acting on a unit charge in air and in this case is also numerically equal to $g$.

In certain media a given charge of electricity produces more force action than does the same charge in air. To illustrate, the charge that will produce a field intensity of $g$ and a flux density of $D$ in air will produce $K$ times this flux density in a specific medium. This, of course, is an exemplification of the fourth basic law. The factor $K$ is called the dielectric constant and corresponds to specific conductivity in the electric circuit and to permeability in the magnetic circuit (as $B = \mu H$). It is apparent from this discussion that the dielectric constant of air is unity. Someone who wishes to attain fame might achieve his wish if he were to discover some natural or synthetic material of which the dielectric constant is as much greater than the dielectric constant of air as the permeability of even a low grade of steel is greater than the permeability of air.

When a one-pound weight has been lifted through an elevation of 10 feet, 10 foot-pounds of work has been done. That is, the work done is equal, *numerically* in this case, *to the elevation.* This simple deduction produces an idea: The height of a mountain could be measured by determining the amount of work done in elevating a given mass from the datum plane to the summit of the mountain. Not a very good idea, the reader may say, because no good instrument for measuring the work is available. The idea is all right but the trouble is in the instrumentation. Now this idea may be used in both magnetics and electrostatics in measuring "elevation." The "elevation" (electric potential) of a charge is measured as *numerically* equal to the work done in carrying a unit charge from infinity (the "sea level" or absolute datum plane of electric potential) to the point at which the potential is to be determined. Expressing this mathematically,

$$E = \int_r^\infty g\, dr$$

where $g$ is the field intensity (force action on a unit charge) and $E$ is the potential at a point distant $r$ centimeters from the point where the inducing charge is located. In the general case $g$ is some function of $r$. To illustrate, if an electric charge of $q$ units is concentrated at a point $P$, the field intensity of another point $r$ centimeters distant from $P$ is, by the second concept, $g = q/r^2$. Therefore the electric potential at the point $r$ centimeters distant from $P$ is

$$E = \int_r^\infty \left(\frac{q}{r^2}\, dr\right) = \frac{q}{r}$$

Thus the seventh concept, the concept of electric potential has been derived. The fact that the field intensity $g$ usually is some function of the distance $r$ adds complications in the practical applications of the concept.

The eighth concept grows out of the previous one. It is more important practically, because ordinarily one is interested not in absolute potential (elevation above the absolute zero of elevation) but in difference of potential

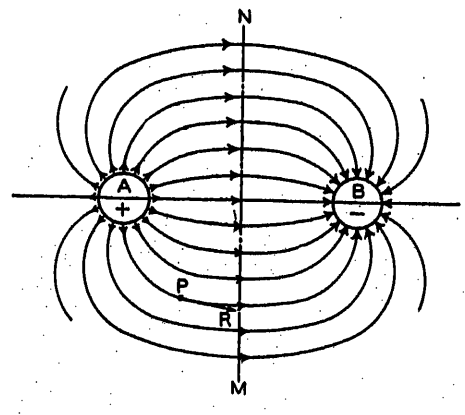

**Figure 4. Sketch showing the resultant dielectric field between the 2 conductors of a single-phase circuit**

(difference in elevation). By way of illustration, the voltage between 2 points, distant $r_1$ and $r_2$ centimeters, respectively, from the point $P$ at which is concentrated a charge of $q$ units is

$$V = \int_{r_1}^{r_2} g\, dr$$

Before integrating this expression, substitute for $g$ its value in terms of $q$ and $r$ as indicated in the previous illustration.

If this equation be differentiated, 2 useful relations result:

$$dV = g\,dr \quad \text{and} \quad g = \frac{dV}{dr}$$

If the field intensity along a path is uniform, then $g$ will be a constant and not dependent on the distance $r$. The voltage between 2 points on this path, located $l$ centimeters apart is

$$V = \int_0^l g\,dr = gl$$

But from the sixth concept, $g = D/K$; therefore,

$$V = \frac{Dl}{K} = \frac{ADl}{AK}$$

where $A$ equals the cross section of the flux path in square centimeters. But $AD = \Psi$ and so

$$V = \Psi \frac{l}{AK} = \Psi S$$

where

$$S = \frac{l}{KA}$$

It will be noted from these algebraic formulations that out of this concept grows the important relation, $V = \Psi S$, where $V$ has the significance of voltage or difference in elevation or pressure, $\Psi$ the significance of flux and $S$ that of resistance. ($S$ sometimes is called elastance and is measured in units known as darafs.) Thus this relation is similar to $E = IR$ in the electric circuit and to $\mathfrak{F} = \Phi\mathfrak{R}$ in the magnetic circuit.

Also the reader will see that elastance $S = l/KA$ is similar to reluctance in the magnetic circuit, where $\mathfrak{R} = l/\mu A$, and to resistance in the electric circuit, where $R = l/\rho A$ (the factor $\rho$ is the reciprocal of resistivity).

Another idea of importance is that the term $g$ is equal to $dV/dR$, that is, to the rate of change of voltage with distance, or to the so-called potential gradient. The quantity $g$, therefore, can be measured in volts per centimeter, volts per inch, or other suitable units. Also since $g = D/K$ it is apparent that $g$ varies directly with the dielectric flux density. This idea is of great value to the engineer in designing insulation because points at which the flux density is high are the danger points as far as insulation breakdown is concerned.

The ninth concept is well known, but the relations between $S$ and $C$ may not be so well remembered. From the relation $q = VC$ a capacitor seems to be a sort of electrical tank into which electrons can be pushed and the more electrons that are crowded into the tank, the greater the pressure $V$ will be. From another point of view the relation $C = 1/4\pi S$ indicates that from the dielectric circuit standpoint capacitance is akin to permeance, or the reciprocal of reluctance in the magnetic circuit.

The first 2 "boxes" contain about all that is needed to solve most of the problems in electrostatics. The difficulty comes in the application of this basic knowledge. Ordinarily 2 somewhat different procedures are followed, either separately or in combination, in the solution of such

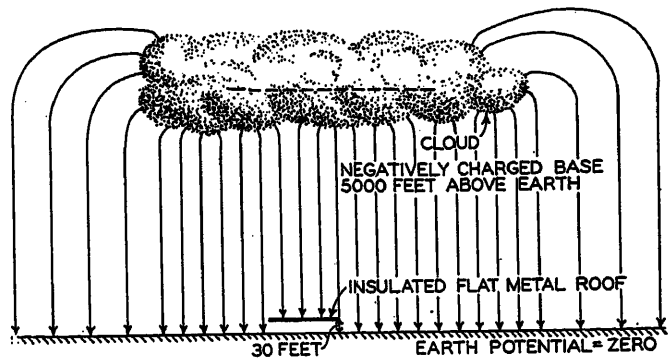

**Figure 5. Sketch showing how an insulated object close to earth may have a potential introduced in it by a charged cloud**

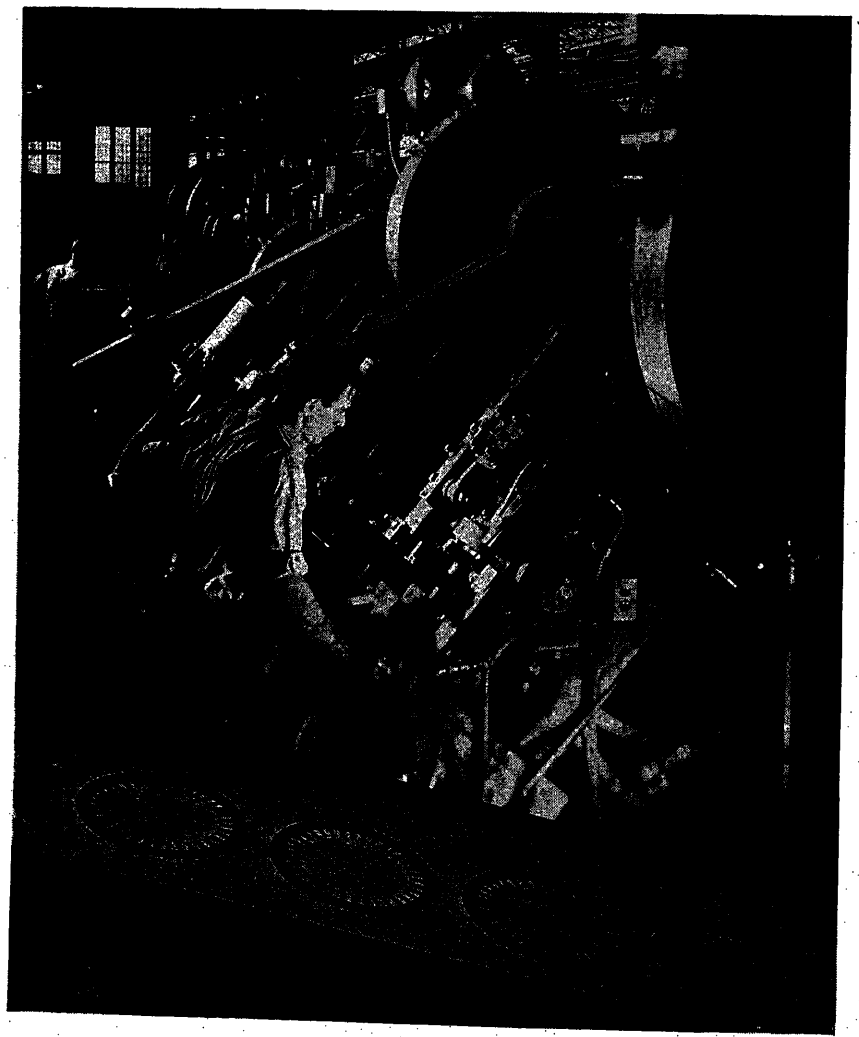
problems. Rather arbitrarily, and with no offense intended to either group, for the present one method may be called the method of the physicist and the other the method of the engineer. One method consists of placing imaginary charges at desired points and computing their effects. The other method accomplishes the same end by visualizing of lines of flux and determining the desired results from formulas applicable to this visualization.

In the twin boxes headed "Physicist" and "Engineer" a few typical examples have been worked out illustrating the application of the 2 procedures. The reader will notice that under the procedure headed "Physicist" a charge is assumed on the capacitor plate or wire, the gradient is then determined at some point, as at $x$ distance, and then the gradient is integrated to obtain the voltage between plates or wires, the capacitance being later determined if desired by the $q = VC$ relation. Under the other procedure the elastance $S$ is determined from the physical dimensions and then the capacitance from the relation $C = 1/4\pi S$. As elastance depends only on physical dimensions and quality of insulation, this method, as far as technique is concerned, is similar to the determination of resistance in the electric circuit and reluctance in the magnetic circuit. This is of practical importance where the design involves forms not reducible to simple geometric figures and where, therefore, mapping of the field is necessary. In general, with this procedure the engineer may use the same methods for solving dielectric-circuit problems that he uses in solving electric- and magnetic-circuit problems. This does not condemn the first procedure, however, for these procedures are but tools in the engineer's tool kit. No one would think much of a man's ability as a carpenter if he used the same saw to rip rough work and to cut off pieces of finishing lumber. Each tool has its advantages and the one used should be the one that will do the job most efficiently.



In the third example, using the second procedure, an equation for the absolute potential $E_A$ of wire $A$ has been set up in terms of fluxes and elastances. In this case there were 2 energized wires and therefore wire $A$ is in 2 component fields: its own field and that set up by wire $B$. There are 2 terms in the equation, therefore. Had it been a 3-phase circuit with 3 wires there would have been 3 terms, and so on. In this example, as in many problems in mechanics, the computer has the choice of using either

the components or the resultant of the components. The component fields, that is the field set up by each wire acting separately are shown in figure 3, the resultant force at a given point $P$ being shown together with the 2 components at this point. The resultant field between the 2 wires is shown in figure 4. It is quite apparent that the component fields, because of their simple geometry, are much easier to work with than the resultant field. In the example under discussion each term in the absolute-potential equation represents the effect of a component field.

As another example of the second procedure, assume that the potential to ground induced by a charged cloud as in figure 5 on a perfectly insulated metal roof must be determined. If the field under the cloud is reasonably uniform the potential of the roof can be estimated with some accuracy, because here, as with other series circuits, the potential of the roof has the same ratio to the potential of the cloud as the elastance from the roof to the earth has to the elastance from the cloud to the earth. Assuming the earth's surface to be at zero potential (which is not often correct) the roof potential is 30/5,000 of the potential of the cloud. In practice the potential never would be indicated by this calculation, because the roof would not be perfectly insulated from the ground.

Finally, there is one other idea that may be of some use in clarifying the reader's thinking relative to the dielectric circuits involved in transmission lines. Assume that water must be circulated through a large block of concrete, such as the Boulder Dam, for example. How could it be done? Someone might suggest that pipes or ducts should be placed in the concrete while the concrete was being poured. Quite true. Pumps then could be connected to these pipes and the water could be circulated without any difficulty except that offered by the resistance of the pipes to the flow of water. Now electrons travel through the air about as freely as water travels through concrete. If electrons are to be transmitted through the air, suitable holes or tunnels must be provided for them to travel in, just as holes through the concrete are provided to permit the circulation of water. When a line gang is sent out to build transmission lines, then, they really are being sent out to string electron holes through the air.

If too much pressure is put on the water in the hole in the concrete, radial cracks or failure of the concrete around the circumference of the hole might be expected. Similarly, if too much voltage (pressure) is placed on the electrons traveling in the holes in the air (wires), failure of the air around the circumference of the hole (wire) will result and the phenomenon known as corona will appear.

Recently placed in operation at the East Pittsburgh (Pa.) works of the Westinghouse Electric & Manufacturing Company, the battery of automatic inclined punch presses shown at the left is part of a new straight-line-production system of manufacturing a-c motors of the standard industrial type, ranging in size from 1 to 50 horsepower. Rotor and stator laminations fall from these presses upon endless belts, which convey them to other conveyors and thence to automatic assembly jigs. Although the new "motor aisle" is intended to specialize in the production of "standard" motors it is said to have facilities for turning out special items without impeding regular production

# Scientific Research Applied to the Telephone Transmitter and Receiver

By EDWIN H. COLPITTS
FELLOW AIEE

**Improvements in the transmitter and receiver, instruments basic to the telephone art, continually have led to a higher grade of service and further economies. Research work has made possible predetermination of performance by calculation, the effect of studies of speech sounds, hearing, materials, and testing methods on the development of instruments giving high quality for conversation is shown by this article, which is based on one of three Iwadare lectures* delivered in 1937.**

LET US recall a scene at the Centennial Exhibition in Philadelphia in 1876. Across a room had been strung wires connecting crude instruments, at one end of the room a transmitter and at the other end of the room a receiver. Dom Pedro, Emperor of Brazil, takes up the receiver and listens while Alexander Graham Bell speaks into the transmitter. The Emperor, astonished at hearing Mr. Bell's voice in the receiver, exclaims in amazement, "My God, it talks."

When at the same place, Sir William Thomson (later Lord Kelvin) took up the receiver and listened to Mr. Bell, the words of this distinguished scientist were, "It does speak," and continuing, "it is the most wonderful thing I have seen in America."

Sixty years have passed and, as a result of continued effort, the use of the telephone has become such an everyday matter that even the ability to talk from one continent to another scarcely excites comment or wonder. It is not surprising that, to the layman, the element of distance seems the most striking factor in the technical development of the telephone art. As a matter of fact, while the conquest of distance has involved much scientific effort, and very ingenious and highly developed methods for the transmission of speech currents, the magic of the telephone still resides in the instruments which provide for the conversion of mechanical energy, namely speech sounds of highly complex wave form, into electrical currents of corresponding wave form, and the reverse process of converting these electrical currents into speech sounds. These instruments, the transmitter and the receiver, are basic to the whole telephone art. As they have been improved by development and design, it has become possible not only to render a higher grade of service but to effect economies in other portions of the plant. For example, the very extensive use of fine-gauge cables was, to a large extent, made possible by the development of more efficient transmitters and receivers. Further perfecting of these instruments promises additional improvements in service and some further economies.

Telephony, restricting the term to ordinary 2-way talking between individuals, involves an element not present in any other service. It does not greatly concern one customer of an electric light or power company whether another customer chooses to use inadequate or inefficient or poorly located lamps or other equipment. That is, each user of the service is, under any ordinary conditions, independent of all other users. In the case of telephony, however, the problem is entirely different; for one user of the telephone is greatly concerned with not only the apparatus furnished to any one with whom he has occasion to talk but also with other factors affecting the use of this apparatus, such as the amount of noise in the room where the apparatus is located, the user's habits of speech, and whether his ability to hear is normal. Telephone instrumentalities must therefore be so designed and the plant so engineered as to meet reasonably wide variations from what may be termed normal conditions, and ratings of performance should be similarly established.

No single factor is more important to a sound development of this art than the subscriber apparatus. The research program basic to the development and design of transmission instruments has itself been a matter of development as a better understanding of the problems unfolded and as the need for research in this or that direction became apparent. The research problem basic to the development and design of transmission instruments may be described as having the following very broad scope: an understanding of their physical operation viewed as electromechanical structures; an understanding of speech mechanism and an accurate physical definition of speech air waves; an understanding of the hearing processes and a determination of how hearing is affected by factors present in telephony. Also, the research program may be said to have included research upon certain materials, the results of which have an important bearing either upon an understanding of the operation of these instruments or upon their practical design. In addition to the development of many methods of measurement and testing applicable to laboratory research and development, of very

* Essential substance of a lecture delivered in the spring of 1937 in Japan under the sponsorship of the Iwadare Foundation. This foundation was established in the Denki-Gakkwai (Institution of Electrical Engineers of Japan) for the following purposes: (1) to send one or two Japanese electrical engineers to the United States each year to study for about one year, and (2) to invite distinguished electrical engineers from the United States to deliver several lectures in Japan once or twice a year. The Japanese society asked the assistance of the AIEE in the guidance of the engineers sent to the United States for study, and also in the selection of distinguished electrical engineers to lecture in Japan. The AIEE board of directors authorized a committee for this purpose in 1931.

EDWIN H. COLPITTS retired early in 1937 as a vice-president of the Bell Telephone Laboratories, Inc., New York, N. Y., after having been engaged in telephone work since the beginning of the century. He has been granted many patents, and has written numerous technical papers. Recently he was awarded the Japanese Fourth Order of Merit of the Sacred Treasure in recognition of his promotion of electrical engineering in Japan.

great importance has been a development of the testing methods which permit of a better final evaluation of the developments based upon the results of this activity.

## Instruments as Electromechanical Structures

The telephone transmitter itself is a complex mechanical and electrical structure. Its general method of operation can be described qualitatively in relatively simple terms, but the operation of few structures is more difficult to define in definite quantitative terms and relationships. For example, there are acoustical problems such as those involved in the air connection between the lips of the speaker and the diaphragm of the instrument. This air connection may involve a short column of air as in those instruments which have a telephone mouthpiece. Connection between the column of air and the working parts of the transmitter may be partially closed by a perforated section. When the operation of the instrument itself is considered, there is involved the mechanical vibration of the diaphragm as it operates on the carbon, and further, the whole question of electric conduction in the small mass of granular carbon itself.

In the receiver which converts telephonic currents into speech sounds, there are very similar acoustical, mechanical, and electrical problems with the exception, of course, of the mechanical and electrical problems introduced by the carbon of the transmitter.

A large amount of research work has been carried on relating broadly to the transmitter and the receiver as electro-mechanical physical structures. The theory of these devices as vibrating systems has been developed so that their over-all performance can be related to the various structural features. Consequently, development and design engineers are now enabled to predetermine by calculation how certain modifications in structure will affect the physical performance of the instrument. In other words, the design process has become very much less "cut and try."

Research has been undertaken and substantial progress has been made on a study of microphonic action in carbon.

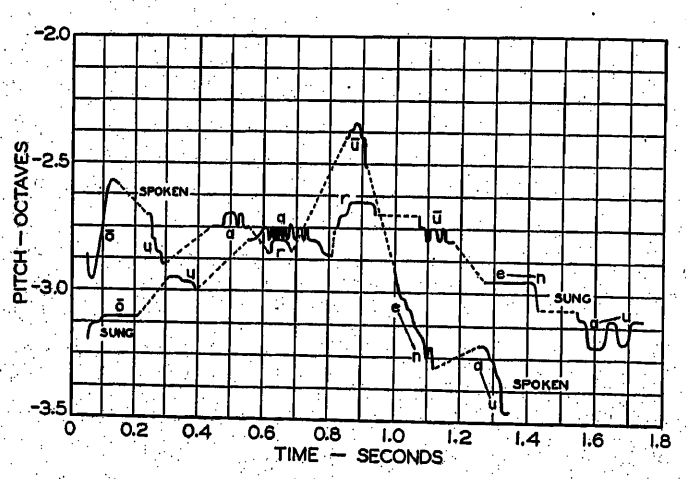


**Figure 1. Melodic curves showing the variation of pitch with time as the sentence "Joe took father's shoe bench out" is spoken and sung**

In order to develop a complete theory of the operation of the transmitter, it is necessary to understand fully what takes place between each carbon granule in the carbon chamber.

## Speech Sounds

The source of any voiced sound is in the larynx. On both sides of this larynx there are 2 muscular ledges called the vocal cords. During breathing these ledges are widely separated, but when a voiced sound is produced, they come close together, forming a long narrow slit. As they come close together, the air passing through the resulting slit is set into vibration producing a sound. It has been generally supposed that the pitch of the tone thus produced was determined by the natural frequency of vibration of the 2 vocal cords, and that by changing the tension of these cords, the pitch of the tone can be raised or lowered at will. The studies revealed that the natural pitch of these cords while a tone is being produced is considerably below that of the pitch of the tone. It is true that the pitch of the tone produced is affected, somewhat, by the elasticity of the vocal cords, but it is principally controlled by the size of the air opening between them. The little plug of air between the 2 vocal cords vibrates through a very much larger amplitude than the amplitude of the cords themselves and is the real source of the sound. The mass of this small plug is controlled by the size of the opening and by the elastic forces pushing it to and fro—namely, the air pressures on either side of it. It is evident that these oscillating pressures will be influenced by the size and shape of the trachea leading into the lungs on one side and by the size and shape of the tongue, mouth, and nasal cavities on the other. The mechanical action involved is analogous to the electrical action in a vacuum-tube oscillator. The sound which is generated at the vocal cords is modified as it passes through the throat, mouth, and nasal passages. The real character of the sound which enables identification of words is wholly dependent upon the manner in which this cord tone is modified by the changing sizes, shapes, and characters of these passages and the outlet to the outside air.

After the various speech sounds leave the mouth, they are transmitted to the ear of the listener by means of air vibration. As an example of the type of disturbance created in the air, consider the sentence, "Joe took father's shoe bench out." This silly-sounding sentence is chosen because it is used for making tests on the efficiency of telephone systems. The sentence, together with its mate, "She was waiting at my lawn," contains all the fundamental sounds in the English language that contribute appreciably toward the loudness of speech. As the sound wave produced by speaking this sentence travels along, each particle of air over which it passes executes a vibration through its original or undisturbed position. The successive positions occupied by the particle as it moves in the complicated series of vibrations corresponding to a spoken sound can be visualized in laboratory investigations from oscillographic records of the corresponding telephone currents.

Each successive particle of air along the line in which the sound is traveling executes a similar complicated series of vibrations but any particular oscillation is performed at a later instant by the particle which is farther away from the source of the sound. The disturbance in the air which represents a spoken sound may then be pictured either, as was first described, in terms of the successive positions of a single particle or in terms of the displacements at any instant of each of the particles along the line of travel of the sound wave. For example, for the sentence "Joe took father's shoe bench out," the disturbance carrying the sound *j* in the word "Joe" is about 1,500 feet from the mouth by the time the sentence is finished.

If an analysis is made of the wave when the sentence "Joe took father's shoe bench out" is spoken, the variations in pitch of the speech sounds can be determined from the vibration rate. Such an analysis is shown in figure 1. The variations in pitch are represented on the vertical axis, zero being taken at 1,000 cycles per second. The duration of the sounds in fractions of a second is represented on the horizontal axis. It may be seen that the pitch rises and falls as the various sounds are spoken. This representation of the pitch variation is called the fundamental melodic stream. It is the melody in the same sense as this term is used in music, although it is evident that the pitch changes do not take place in musical intervals as would be the case if the sentence were sung.

To show the contrast, a graph was made when the sentence was intoned on the musical intervals *do, re, mi, fa, mi, re, do.* An analysis of the graph gave the result shown in figure 1. In the case of the sung sentence the pitch changes are in definite intervals on the musical scale, while for the spoken sentence the pitch varies irregularly, depending upon the emphasis given. The pitch of the fricative and stop consonants is ignored in the musical score, and since these consonants form no part of the music, they are generally slid over, making it difficult for a listener to understand the meaning of the words. A singer's principal aim is to produce beautiful vowel quality and to manipulate the melodic stream so as to produce emotional effects. To do this, it is necessary in singing to lengthen the vowels and to shorten and give less emphasis to the stop and fricative consonants. It is for this reason that it is more difficult to understand song than speech.

There are 2 secondary melodic streams of speech represented by the second and third curves from the bottom of figure 2, which are due to the resonances imposed upon the speech sound by the throat and mouth cavities. The numbers on these curves give the number of the harmonic which is reinforced. These 2 secondary melodic streams are not sensed as changes in pitch, but rather as changes in the vowel quality. Then there is a fourth stream, or, it would probably be better to say, a fourth series of interrupted sounds which are very high in pitch and are the sounds which enable us to identify the fricative consonants. The secondary melodic streams produced while speaking the same sentence are approximately the same for different persons, even for a man and a woman, while the fundamental melodic stream is usually quite different. This latter stream is not used in identifying words, but it is

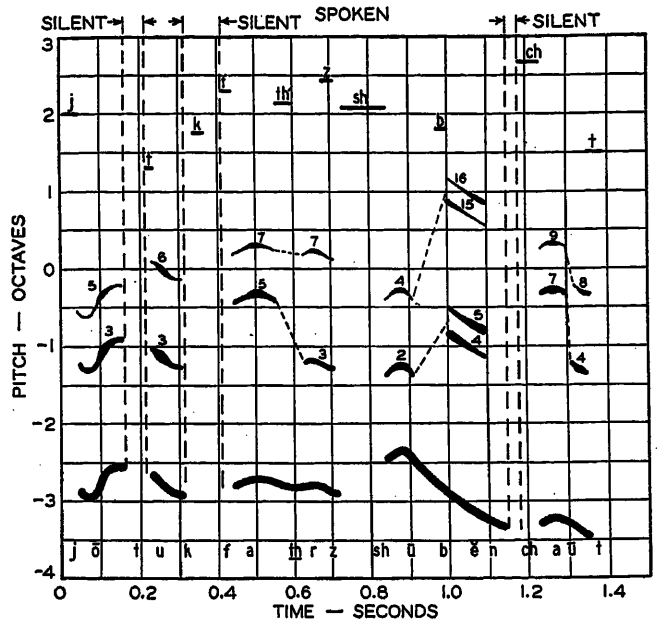

**Figure 2. Melodic curves showing the variation of pitch with time as the sentence "Joe took father's shoe bench out" is intoned on the musical intervals do, re, mi, fa, mi, re, do. The pitch changes in regular intervals rather than in irregular intervals as shown in figure 1**

used sometimes to give different meanings to the same words.

As one listens to this sentence he hears the variations in loudness as well as in pitch. Loudness is related to the amplitudes and frequencies of the components of the tone, but this relationship is very complicated. It is dependent upon the action of the ear, including the nerve mechanism carrying the message to the brain. This relationship has been under study for several years so that it is now possible to calculate from physical measurements the loudness for a typical ear and also to devise instruments for measuring approximately the loudness of any sound. The result of using such a device for recording the variations of loudness in the spoken sentence which has been discussed is shown in figure 3. For comparison, the variations in pitch are also shown in this figure.

It is not possible here to describe the devices by which the energies and frequencies involved in speech are measured accurately, but the results of this research work are interesting. When this sentence is spoken fairly rapidly, it will contain about 200 ergs of energy. About 500,000,000 ergs of energy pass through the filament of an ordinary incandescent lamp each second. This shows that the acoustic energy in this sentence is very small. An examination of the wave produced by this sentence shows that the vowels contain considerably more energy than the consonants. Exact measurements have indicated that in ordinary conversation the ratio of the intensity of the faintest speech sound, which is *th* as in "thin," to the loudest sound, which is *aw* as in "awl," is about one to 500. The actual power used in producing the various sounds depends, of course, upon the speaker and the emphasis with which he pronounces the sound. The

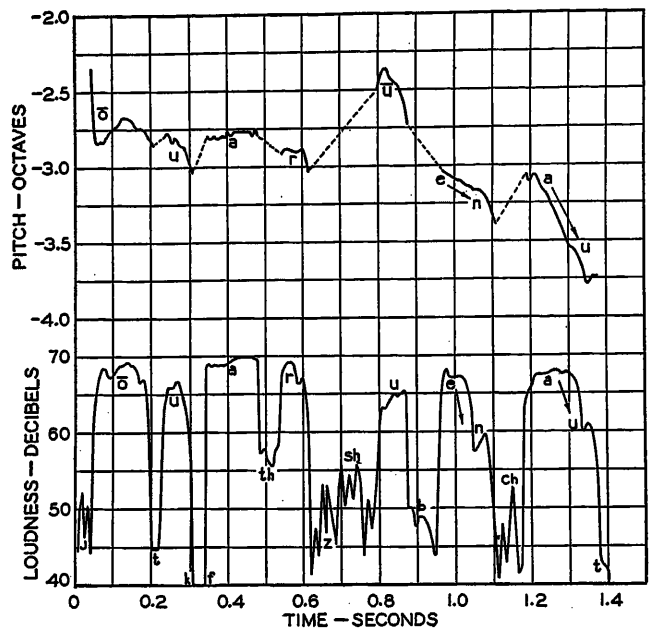

**Figure 3. Graph of the loudness of the various sound elements when the sentence "Joe took father's shoe bench out" is spoken**

power in an accented syllable is 3 or 4 times that in a similar unaccented syllable. Measurements upon voices during a conversation have indicated that the average power in the speech produced is 10 microwatts. Some speak with more and others with less than this power. Tests on a sample group show that 7 per cent speak with less than one sixteenth the average power, 18 per cent use powers lying between one quarter and one half the average, and 4 per cent between 4 and 8 times the average. No speakers were found to use more than 8 times the average for conversational purposes.

As a conversation proceeds, the speech power varies from zero during the silent intervals to peak values which frequently are 100 times the average power. Examination of one-eighth-second-intervals throughout a typical conversation shows that for 17 per cent of them the peak power lies between 8 to 16 times the average over a long interval. It is found that the most frequently occurring value of the peak power is about 10 times the average.

Although a typical voice of a man and a typical voice of a woman are alike in that they use the same average power and variations of power from this average, they are different in other respects. It is well known that the pitch of the voice of a woman is about one octave higher than that of a man. It was not known, however, until laboratory experiments revealed it, that the intensity of the components having vibration rates above 3,000 cycles per second was definitely greater for voices from women than from men. For some reason which is not very evident, women use higher pitch sounds for producing the fricative consonants, and this results in greater power in the regions of higher pitch. Every one who is familiar with transmission systems knows well that these high-frequency components are nearly always eliminated. While these sounds are not of controlling importance in properly understanding speech, it is evident that the women's voices are somewhat handicapped as compared with men in systems which eliminate them.

## Hearing

Paralleling research on speech sounds, hearing has been investigated. Broadly speaking, the aim has been to arrive at an accurate physical description and a measure of the mechanical operation of human ears in such terms that they may be related directly to the electrical and acoustical instruments. The keenness of the sound-discriminating sense has been measured, and the smallest distortion which the mind can perceive, and how it reacts to somewhat larger distortions, has been determined. This information is utilized in determining a reasonable basis of design both for separate instruments and for transmission systems as a whole, to give a proper balance between cost and performance.

One of the first steps was to determine in a quantitative way the performance of ears as machines. It was obviously important to know how faint a sound the ear can hear, and also how loud a sound the ear can tolerate. With the advent of the vacuum tube, it was possible to develop methods of accurately measuring the intensity of faint sounds and of readily producing such sounds. Figure 4 gives the results of measurements made to determine the limits of hearing. This graph is called the auditory sensation area. The lower solid curve represents the minimum sound that an average young person can hear. The abscissa gives the frequency of the pure tone, and the ordinate the sound pressure in dynes per square centimeter. The top solid curve represents the maximum intensity of sound that the ear is capable of handling. This curve was determined by noting that intensity which produced a feeling sensation. Intensities slightly higher than this result in pain and in some instances serious injury to the ear. The dotted lines on either side complete the enclosure and represent the upper and lower limits of pitch that can be heard. From this figure, the upper or lower limit of pitch obviously is greatly dependent upon the intensity at which the sound is produced. It may be seen that near the middle range of frequencies, the pressure range is one million to one. The pitch range of pure tones is from about 16 to 25,000 cycles per second.

These results are for young adults, and it may be of interest to note that as one becomes older the hearing acuity, at the higher frequencies particularly, becomes less. In table I are shown some measurements to determine what the effect of age would be upon the hearing acuity; these are average values obtained from measurements on a large number of persons.

Another important measurement of average hearing is that concerned with minimum perceptible differences in pitch and in intensity. Careful measurements on large groups of people have given reliable data. Near the threshold changes in intensity of about 4 decibels are necessary to be perceptible, while at fairly high intensities about $1/4$ decibel is all that is necessary for the change to be perceived. Minimum perceptible differences in pitch

vary from about 0.0025 octave to 0.19 octave, depending on the frequency and the intensity. The results of this line of investigation have an important bearing on the physiological theory of hearing, and another important result has been the development of methods of determining the degree of impairment of hearing.

In telephony we are, of course, not directly concerned with simple sounds, but with the highly complex sounds of speech, and these are on actual telephone circuits generally associated with extraneous sounds which may be grouped under the broad term of noise. Further, telephone instruments are not perfect, and could be made to approach perfection only at a great expense. In order to arrive at a quantitative understanding of the importance of departures from perfection in telephone transmission elements and conditions of use, the general procedure in very general terms has been as follows: Transmission systems so nearly perfect that even the keenest ear could not find a flaw in their transmission performance are set up, and then measured imperfections or variations are introduced.

By this general process, the effect of noise of chosen intensities either as noise present in the telephone receiver or as noise in the room was determined. Similarly, the effect of a line or other characteristic such that voice frequencies above a certain value or below a certain value were not transmitted, was determined. The effect of introducing a highly resonant element or of a nonlinear element was studied. The range in loudness of speech necessary for best reception was likewise measured.

As noise became recognized as a very real factor, a standard basis for noise measurements was established. Consequently it is now possible to measure noise on a telephone circuit or in a room, and to state the result in terms of a standard unit.

## Materials

In the practical design of modern telephone instruments we owe a large debt to the chemist and the metallurgist. Modern molding materials and processes are utilized in order to secure forms of apparatus satisfactory from the standpoint of appearance and of mechanical strength. The newer types of permanent magnet steel provide possibilities of light-weight and very efficient magnetic structures.

It is a most striking circumstance that commercial telephony is dependent upon the performance of a small mass of carbon granules in the transmitter. No single material entering into the construction of telephone apparatus has therefore greater importance. In America at least, transmitter carbons are largely derived from a certain specially selected anthracite coal. In its natural state, this coal exhibits none of the characteristics required for its use in a transmitter. These characteristics or properties are secured by heat treatment. These heat-treatment processes were for many years the result of empirical development and were not well understood nor, as is now recognized, adequately controlled. This resulted in a product of uncertain quality. An important task of the Bell Laboratories was therefore to study each step in the process of producing carbon and to develop a process definitely specified at each step, which would be capable of giving the desired uniform quality. The results so far obtained have had very important reactions upon transmitter performance. The Laboratories have also set themselves the more elementary task of understanding the fundamental properties of carbon contacts. One important element of this research is to determine the causes of resistance changes produced when the compressive force on a mass of carbon granules is changed. It is too early to report results from this research, but it seems clear that granular carbon will be an important element in the design of transmitters for many years to come, and we should seek to obtain complete fundamental knowledge of its operation.

**Table I. Decibel Loss in Hearing With Age**

| Frequency | 60 to 1,024 Cycles | 2,048 Cycles | 4,096 Cycles | 8,192 Cycles |
|---|---|---|---|---|
| Ages 20–29 (96 ears) | 0 | 0 | 6 | 6 |
| Ages 30–39 (162 ears) | 0 | 0 | 16 | 11 |
| Ages 40–49 (84 ears) | 0 | 2 | 18 | 16 |
| Ages 50–59 (28 ears) | 0 | 5 | 30 | 32 |

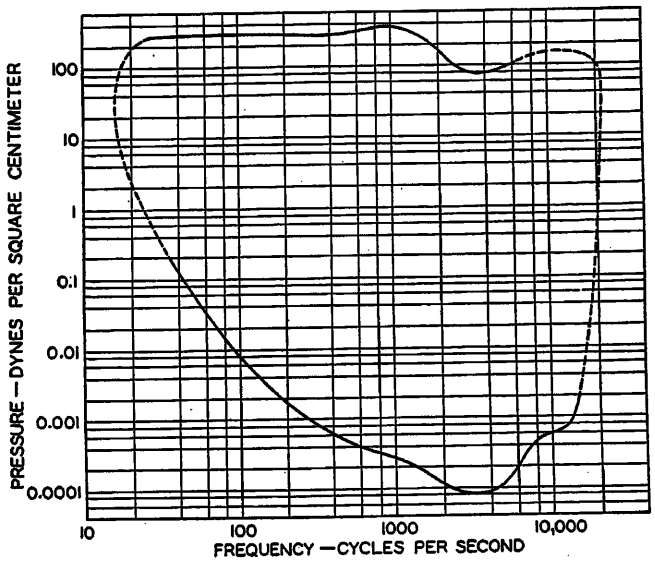

**Figure 4. Auditory sensation area for the typical ear of a young adult**

## Testing Methods

Broadly speaking, methods of testing have been developed, first, to enable the development and design engineer to determine quantitatively the various performance factors of the apparatus under development, and second, to determine how well the apparatus which has been developed performs under service conditions. In the Bell Laboratories, methods have been developed during the last 20 years for measuring the physical constants of the apparatus involved so that this apparatus may be an-

alyzed as electromechanical structures. Further, in the design of telephone transmission apparatus we are concerned with a power transmission system in which the design engineer has no control over the power source, the human voice, nor over the receiving agency, the human ear. His control is limited to the conveyance of power from speaker to listener. In the Laboratories, therefore, we have recognized that it is necessary, at least with our present knowledge, to supplement physical measurements by measurements involving speech sounds and the human ear. Some years ago, these tests consisted of comparisons between different instruments or transmission elements made by the process of talking first over a circuit containing, for example, one instrument, and then over the same circuit containing a different instrument. Dependence was placed wholly upon the listener's skill to detect differences in volume, quality, and intelligibility. It was recognized that this method of testing left much to be desired. Owing to the limitations of the human ear, small volume differences could not be detected, but even more important, this simple test furnished no very accurate measure of speech distortion affecting intelligibility, and obviously no definite information as to the relation between volume, various types of distortion, and over-all effectiveness.

Doctor George A. Campbell, in 1910, proposed a method of testing which has been highly developed in the Laboratories. This method, termed "articulation testing," measures the relation between the reproduced and impressed sounds from the standpoint of effects on intelligibility of different kinds of distortion. This method has been described in several publications. Briefly, in this method, lists of syllables chosen at random and usually meaningless monosyllables are called over the circuits to be rated, and the percentage of syllables correctly understood gives a measure of the circuit performance. Further, the method has been extended to give quantitative measures in terms of the recognizability of reproduced speech sounds, of the effects of loudness of these sounds, and of the noise which may be present.

While various physical tests and the articulation test method are exceedingly useful tools in the hands of the research and development engineer, they do not give a direct measure of the transmission service performance of a circuit in terms of the ability of the user to carry on a conversation under actual commercial conditions. This ability of the user to carry on what may be termed a successful telephone conversation depends not only upon the performance of the telephone instruments and circuits but also, to a substantial extent, upon the users' own performances—the subject material of conversation, how they talk into the transmitters, and how they hold the receivers —and upon the room noise conditions. In other words, there are a number of factors random in nature which, while beyond the control of those who design and engineer the telephone plant, must be taken account of in rating the service performance.

Much thought and effort have been given to the problem of how best to determine transmission service performance. Very briefly stated, we have been led to the following steps: In order to take suitably weighted account of all the factors involved, service performance ratings should be based on service results, that is, transmission service performance should be measured by the success which users of the telephone circuit have in carrying on conversations over the circuit. With the various factors in mind, we have fixed upon what we have termed "effective transmission" ratings for transmission plant design. These ratings are based on a determination of the *repetition rate* in normal telephone conversations.

As the effect of a change in a circuit depends upon its initial characteristics, it is necessary in order to be able to compare numerical results to have a basic circuit for reference. By suitable choice of basic circuit, it is possible to express the effects of changes in any one transmission characteristic in terms of the attenuation of the trunk. For example, the effect of changes in sidetone level in the subscriber's set can be expressed as so many decibels change in trunk attenuation.

## Association of Transmitter and Receiver

In order to furnish a convenient 2-way talking circuit over a single pair of wires, the transmitter and the receiver at each end of the circuit must be continuously associated in the circuit. This has been accomplished by various circuit arrangements since the early days of the telephone, and as every user of the telephone knows, leads to the condition that when speaking into the transmitter one hears his own voice in the receiver. Local speech so heard is designated as sidetone. The Laboratories have carried on research in order to determine the effect of sidetone on the over-all efficiency of the circuit. Sidetone above a certain volume has been found to decrease the conversational efficiency of the circuit. Parallel with the study of the effects of sidetone, research has been carried on on methods which could be applied to limit sidetone in amount to more nearly its optimum value. This has led to the development of what are known as anti-sidetone circuits, which do not eliminate sidetone but reduce it to an amount which is more nearly that found to be desirable.

An important step in the association of the transmitter and the receiver is represented by the handset which provides a rigid mechanical connection between the 2 units. This rigid mechanical connection introduces mechanical coupling between the receiver and the transmitter, which had to be given very serious consideration in order to avoid speech distortion.

## Trends in Instrument Development

I have broadly indicated fields of research which underlie the development and design of the telephone transmitter and receiver. It will now be of interest to note what application is likely to be made of the results of what has amounted to an enormous total of scientific effort. In this connection, it may be well again to emphasize that station apparatus is intimately associated with the user, and has therefore to be designed to fit him, his habits of using the telephone, and the conditions attending such

use. The handset has to be designed to fit his head, the holes in the dial to fit the size of his finger, the bell to be loud enough, and so on. Our effective transmission rating system has been set up in an attempt to rate the performance of the telephone when employed by the customer in

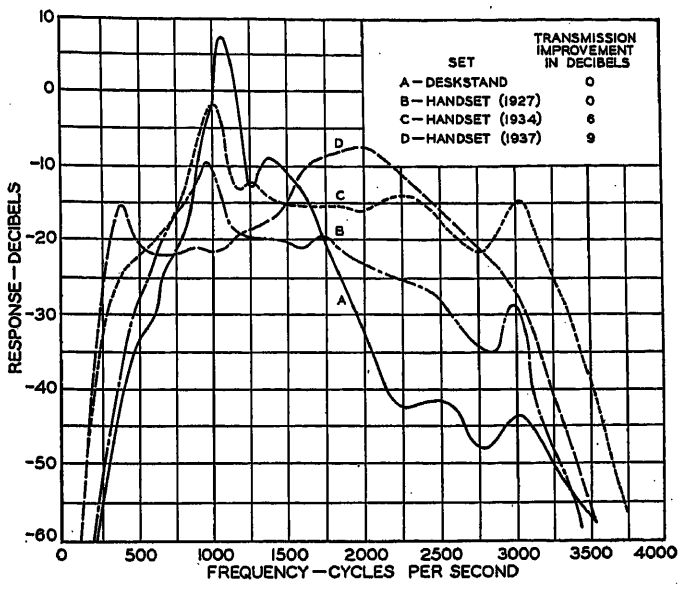

**Figure 5. Comparison of the response-frequency characteristics of telephone instruments**

the way he wants to use it, under the conditions surrounding him. For this reason, this method of rating has been found particularly valuable in the development work on instruments.

Because of the wide range of customer usage and conditions, a number of factors have to be taken into account in the design of the apparatus. Also, because this apparatus is located on the customer's premises, where it is relatively inaccessible to the telephone personnel, it must be capable of standing up without undue trouble under this wide range of usage and conditions. To strike a proper balance in meeting all these factors requires an intimate knowledge of the field conditions as well as of the development and manufacturing possibilities. A continuing close contact with field experience is employed to modify the designs toward securing the proper balance to meet these factors.

In order to indicate more clearly the present trends in design, I shall refer briefly to the earlier art. In the early development of transmitters and receivers, the matter of getting efficiency was of primary importance since this could be evaluated directly in terms of the amount of copper required in the connecting line. The early transmitters, which were of the same construction as the receiver, depended on the generator action of a diaphragm and coil and developed sufficient power to be heard over only a few miles of heavy-gauge wire. Some amplification was necessary before telephone communication could begin to assume the proportions of a widespread service. This amplification was obtained at a reasonable cost in the carbon-contact transmitter. Transmitters of this type are in the order of 60 decibels more efficient as transducers of acoustic to electric energy than the earlier type.

Both the transmitter and the receiver operate by means of diaphragms which have natural periods of vibration. These resonances and the resonances of the air spaces on each side of the diaphragm were used to obtain as efficient a transfer of energy as possible. In the early design, a great deal of attention was also given to locating these resonances at the portion of the frequency range where they would tend to increase the intelligibility of the reproduced sound. As a result, both instruments were made very efficient in the region of 1,000 cycles, which lies within the range where the ear and the sensation of loudness are most sensitive.

It was recognized that these resonances caused undesirable distortion, but under the conditions the resulting increase in efficiency more than compensated for this disadvantage. As time went on, the diaphragm resonances came to be looked upon as practically inherent in commercial transmitters and receivers, because no way was known of eliminating them without making a very material sacrifice in the efficiency of the instrument.

About 20 years ago, the development of the vacuum-tube amplifier and the high-quality condenser transmitter made it possible to demonstrate and measure quantitatively the advantages of reducing distortion. These high-quality instruments, the improvement in measuring technique, and the development of improved methods of de signing vibratory systems offered the promise of providing instruments in which the resonance effect could be reduced without unduly affecting efficiency.

The first commercial instrument for station use, which demonstrated the possibility of carrying out this promise, was the transmitter employed in the handset first supplied by the Bell System in 1927. This transmitter had to meet the requirement of giving the same transmission service as transmitters of the deskstand type, and at the same time meet the very exacting requirements imposed by the handset to make it free from howling and capable of performing over a wide range of positions. The diaphragm resonance was damped to a large extent by the use of paper rings and, by lightening the structure, the point of maximum response was moved up in frequency so that it no longer coincided with the peak of the receiver. The effect of this was not only to broaden the response characteristic and improve intelligibility, but also to reduce the gain in the local howling circuit which is, of course, a maximum when both transmitter and receiver have their greatest efficiency at the same frequency. The same separation of peaks resulted in the received speech being less loud, but in spite of this the over-all performance was equivalent to that of the best deskstand type of instrument then available.

With this accomplishment, further work was directed toward maintaining the lower distortion and increasing the efficiency. The transmitter introduced in 1934 represented a marked improvement along this line. This instrument still further broadens the transmitted frequency range and is used with about the same efficiency in deskstands, handsets, wall sets, and coin-collect sets.

A new type of handset is being introduced in the Bell System in 1937 which, in addition to having a more pleasing and simplified design, will incorporate the new transmitter mounted in such a way as to make fullest use of its ability to transmit efficiently over a wide-frequency band.

During this evolution of the transmitter, the knowledge which had been gained as to the importance of transmitting different widths of frequency band over commercial telephone circuits led to the establishment of the range from 250 to 2,750 cycles for designs of new circuits. It was not the intention in the establishment of this range that circuits should not do better than this where it is possible without materially increasing cost, but that all circuits should be at least as good as this. The establishment of this frequency range took into account a number of factors of which a very important one is that the over-all utilization of this range from the sound entering the transmitter to the sound output of the receiver provides a grade of transmission which is highly satisfactory for the reproduction of conversational material.

The establishment of this frequency range played a part not only in the design of circuits, but also in guiding the evolution of the transmitter and receiver. The transmitter last referred to meets this requirement very well. In fact, its efficiency is fairly uniform for a frequency range extending beyond 4,000 cycles.

The next step in the process was to improve the performance of the receiver. A pronounced resonance at 1,000 cycles was no longer necessary since means had been found to improve the efficiency of instruments in other ways than by concentrating all the resonances at one frequency. The importance of the higher frequencies in transmitting and reproducing the transient sounds characteristic of the consonants in speech led to placing more emphasis on these frequencies and attempting to produce more uniformly the band of frequencies which was set as a limit for circuits. This has now been accomplished in a practical fashion in the receiver which is being introduced in 1937.

The effect of this evolution in the design of station instruments may be brought out by a comparison of the over-all response characteristic—that is, the relation of the sound delivered to the ear to the sound available at the transmitter—for a typical telephone connection having in one case, both terminal instruments of the 1920 type and, in the other case, the terminal instruments of the new 1937 type (figure 5). In this typical circuit, the trunk has been taken as free from distortion so that its effect will not influence the indicated performance of the instruments, although the circuit does include 2 22-gauge loops each 3 miles long.

At the resonance point of the old instruments, just over 1,000 cycles, the over-all response in going to the new instruments is reduced by almost 30 decibels while the response in the range from 2,000 to 3,000 cycles is increased by over 20 decibels. In the frequency range from 500 to 2,000 cycles, the circuit employing the older instruments shows a variation of over-all response of over 30 decibels. For the new type, the variation for this same frequency range is reduced to 15 decibels, and, furthermore, this variation of 15 decibels applies approximately for the range of from 250 to 2,750 cycles which was mentioned as the transmission range requirement for the design of new circuits. In regard to the variation of 15 decibels in this frequency range, there is good indication that this response is more desirable than one of no variation, from the standpoint of having the telephone performance approach that of direct air transmission.

In addition to these improvements in frequency response and efficiency, the intensive development program on these instruments has improved materially the stability of the carbon transmitter under service conditions. This is an important factor in extending the useful life of these instruments and in reducing the cost of maintaining the desired transmission performance.

---

## Proposed Recommendations for Measurement of Surge Voltages and Currents

IN THE July 1936 issue of ELECTRICAL ENGINEERING the subcommittee of the AIEE committee on instruments and measurements presented a report giving the revised values for 60-cycle sphere-gap calibrations. The values for impulse voltages, however, were held pending development of instructions for their use. A new report by the same committee now has been made available containing the proposals defining the applications and use of sphere spark gaps for both 60-cycle and impulse measurements. This report also corrects certain errors made in the statement of 60-cycle values as published in July 1936.

The recommendations included in the report were formulated in recognition of a general need for a surge measurement standard from which could be derived necessary measurement technique for the surge-testing codes for apparatus and materials. Particular code requirements will necessitate varying measurement technique, and it is expected that this proposed standard will serve as a source from which can be drawn all the necessary measurement recommendations required. Accordingly, it is urged that it be viewed and used in this way. For specific measurement recommendations applying to a particular apparatus, the test code for that apparatus should be consulted.

When approved by the AIEE standards committee, all of the material contained in the subcommittee report will become a part of the proposed complete revision, now under way, of the present AIEE Standard No. 4, "Measurement of Test Voltage in Dielectric Tests."

Those interested in the subcommittee report on the "Proposed Recommendations for Measurement of Surge Voltages and Currents and the Sphere Gap Calibration Standards" may obtain a complete mimeographed copy, without charge, by writing to H. E. Farrer, secretary AIEE standards committee, 33 West 39th Street, New York, N. Y.

# Forty Million Kilowatt-Hours for a Fair

ILLUMINATION PLANS for the 1939 Golden Gate International Exposition on San Francisco Bay call for consumption of an estimated 40 million kilowatt-hours of energy during the 288 days of the fair, from February 18 to December 2, 1939.

The Exposition's site is a 400-acre island, created by dredging in the center of the harbor near the mid-point of the San Francisco–Oakland Bay Bridge. Power will be delivered at a 16,000-kva substation on this "Treasure Island" through 3 submarine cables, each 9,000 feet long, from the mainland. Distribution will be made by 10 miles of 4,000-volt underground 3-phase feeders, approximately 25 miles of streetlighting cable, and an undetermined length of secondary.

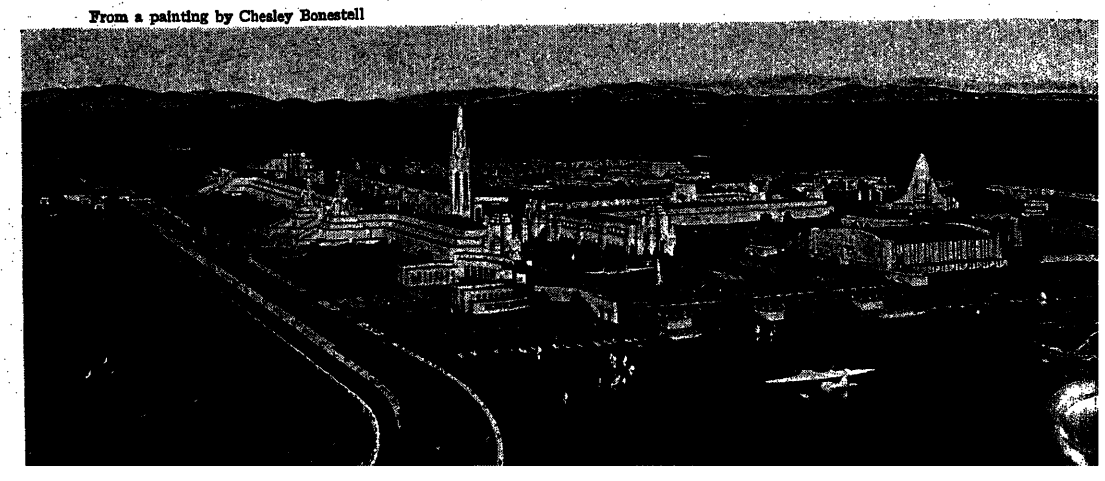
Approximately $1,000,000 is budgeted for illumination and electrical installation, and intensive field work will be started in the spring of 1938 after underlying water and sewer lines have been laid. Installation is divided into permanent and temporary classifications, for 3 buildings will remain after the close of the Exposition as air terminal building and hangars for the municipal airport that will take over the island. Other buildings will be razed. Decorative installations will use knob-and-tube work, but all interior wiring will be in conduits.

Exterior lighting, expected to set new standards of beauty, has been worked out by a committee of illumination engineers. The plan calls for extensive use of the new "fluorescent tube," a development not yet on the market. These 15-watt gas-filled tubes, mounted in trough reflectors and used for floodlighting, give spectacular effects particularly in pink, blue, green, and white.

Searchlight scintillators, marching cylindrical lanterns, moonlighting, flush lights, steam urns, and water effects have their necessary place in the night picture, and unusual methods of their use are being worked out. At some points, as in the Court of Reflections, lighting will be restrained to encourage a placid mood for greater enjoyment of the scene; at other points, such as the 40-acre Midway, the only restrictions will be against excessively bright exposed lamps that would violate the harmony of the whole.

"Stunts" will be few in number, for the intention is to create a pastel picture of mystery and fantasy, aiding in the interpretation of the basic creation of architects, landscape artists, sculptors, and colorists. Utilitarian roadway lighting will be so designed that it will not detract from the illusion of a white "jeweled city" floating upon the water, and the $50,000,000 fair will be blended into an artistic architectural unit by day or night, rather than a disconnected assemblage of exhibit buildings.

Architecturally, the Exposition will be a series of masses carried toward the skyline by stepped setbacks. These setbacks will be flooded in varying intensities or graduated colors to preserve their positions, with the monotony of normal floodlighting broken by highlights or color changes based upon flags, niches, and architectural elements. Flatness will be relieved also by large circles of color, by the shadows of palm trees, and by ultra-violet radiation playing from concealed projectors on fluorescent paint.



Trees generally will be treated as dark masses, or as silhouettes against glowing backgrounds. Lip lighting and jets will mark the rims of pools, and a feature will be a reproduction in the Port of the Trade Winds of Old Faithful geyser, playing to its full height of 150 feet at brief intervals and lighted by searchlights in changes. At the opposite end of the mile-long island will be an aurora of scintillator beams, created by 24 arc searchlights of 36-inch diameter.

Supplemental to standard lighting will be a power system for stage and spot lighting which can be adapted to special pageants as required. Interiors of exhibit buildings will be illuminated uniformly by day and night, with no windows to mar the planned effectiveness of displays. A spectacular feature in several courts will be cylindrical lanterns, from 60 to 75 feet high and 6 feet in diameter, lighted by concealed tubes within.

Colors will be restricted to harmonious groups of 2 or 3 in each court; chiefly employed will be amber, green, red, apricot, blue, peach, gold, pink, and magenta. The 400-foot central tower, an opportunity to the illuminator, will be a light amber at the base, shading into white of increasing intensity toward the spire. It will be topped by a searchlighted phoenix, rising from a bright red illumination at its base. The interior of the tower, viewed through tall arches, will be amber at the base and blend into a rose red at the upper level.

More than $10,000,000 worth of buildings for this 1939 World's Fair are under construction in the fall of 1937, and the programs of governmental and industrial participation are equally advanced. Except for firms planning to erect their own buildings, electrical displays will be concentrated in a hall of electricity and communication. Central co-ordinating displays planned for this phase of the exhibit program include great relief maps of the Pacific area, painted by "black light" on fluorescent paint to develop existing communication and power lines from virgin country in a twinkling.

From a painting by Chesley Bonestell

# Monthly Earnings of Engineers, 1929–34

**In this, the seventh article[1] of a series reporting a survey of employment in the engineering profession by the United States Bureau of Labor Statistics, data relative to the monthly rate of compensation received by engineers solely for engineering services in which they were engaged at the end of 1929, 1932, and 1934, are presented. Comparisons may be drawn among professional classes, ages, and educational background.**

IN 1929, the range in monthly engineering earnings of professional engineers was very great. Some 79 engineers reported earnings of less than $60 per month, while 168 earned more than $1,880 a month. The median monthly earnings of the 28,511 reporting engineers was $289. One-quarter earned more than $415, while only 10 per cent had earnings greater than $609 a month.

Between 1929 and 1934 there were progressive declines in monthly engineering earnings. While the sharpest absolute decreases occurred at the higher levels of earnings, the greatest percentage decreases took place at the lower earnings levels. Almost two-thirds of the decreases occurred between 1929 and 1932.

Comparison of earnings by professional class, without regard to age, and the consequent effect of the varying age distributions shows that in 1929 the upper 10 per cent of mining and metallurgical engineers, highest at this level, reported earnings of not less than $792 per month as against $515 a month for civil engineers, who were lowest at this level. Second in order came chemical and ceramic engineers, followed by mechanical and industrial, and electrical engineers. For the upper 25 per cent of the reporting engineers the order of the professional classes was the same, monthly engineering earnings ranging from not less than $372 for civil engineers to not less than $503 a month for mining and metallurgical engineers. At the middle and lower earnings levels, the differences in earning capacities of the 5 professional classes were less marked, although in each instance mining and metallurgical engineers and electrical engineers occupied the upper and lower extremes, respectively.

In 1932 and 1934 the order of the professional classes at the 2 higher earning levels was essentially the same as that noted for 1929. At the 3 lower earning levels shifts occurred in this order in 1929, and there were further shifts in 1932 and 1934.

On an age basis the 1929 monthly compensation for engineering services of the lowest tenth of reporting engineers was more than twice as high for those in the age group 48 to 55 as for those of 23 years. At the upper 10 per cent earnings level, maximum earnings of $1,050 a month were reached in the sixties. Similarly, at the average and at the upper and lower quarters of earning levels age 60 was the turning point.

For men of identical ages in 1929, 1932, and 1934 the data reveal that the greatest impact of the depression, as far as engineering earnings were concerned, fell upon men with from 2 to 5 years' experience.

Although the 1929 data on engineering earnings evidence an advantage in favor of men who have engineering degrees, this advantage was less clearly defined than was the case with earned annual incomes. However, the extra years of experience which the "other" engineers had while the graduates were in school permitted of their obtaining higher earnings than graduates only up to a point corresponding to 5 years after graduation. Even at 2 years after graduation the differentials in earnings between the 2 groups were slight. Similarly, at 4 years after graduation, while at the median level graduate earnings ranged from $225 for first-degree electrical engineers to $250 a month for first-degree chemical and ceramic engineers, among the "other" engineers they ranged from $200 for engineers with secondary school education to $229 a month for mechanical and industrial engineers with incomplete college courses.

With advancing age there was a considerable advantage in engineering earnings in favor of the graduates. There was also a distinct variation in the earning capacities among both graduate and "other" engineers.

The monthly engineering earnings of graduates continued to increase several years beyond the point of maximum earnings of "other" engineers. The earnings of the latter either remained stable or declined at 30 years after graduation.

While graduates who were 23½ in 1929 and 28½ in 1934 reported increased earnings for all kinds of engineering, except mining and metallurgical, no increases were reported by any of the "other" engineers of corresponding ages. For older engineers, however, the decreases apparently affected both graduates and "other" engineers in almost equal measure.

For men of identical years of experience, the earnings received in 1934 by both graduates and "other" engineers were all less than those obtained in 1929. The decreases reported by men with 5 years' experience were, in general, greater than those of men with 2 or with from 10 to 37 years' experience.

## Scope and Method

The earned annual incomes of any professional group are made up of earnings from professional work plus, in

1. An article prepared by Andrew Fraser, Jr., of the Division of Hours, Wages, and Working Conditions, Bureau of Labor Statistics, United States Department of Labor, which article was published in the November 1937 issue of *Monthly Labor Review*. Articles reporting other phases of this survey were published in ELECTRICAL ENGINEERING as follows: "Professional Aspects of Engineering Education," August 1936, pages 863–7; "Unemployment in the Engineering Profession," February 1937, pages 216–23; "Employment in the Engineering Profession," May 1937, pages 524–31; "Security of Engineering Employment," June 1937, pages 655–61; "Engineering Income and Earnings," September 1937, pages 1089–1104; "Sources of Engineering Income, 1929–34," November 1937, pages 1353–58. A detailed report of the survey will be published later in bulletin form by the Bureau of Labor Statistics.

some cases, those received for other services. They are affected, moreover, by periods of partial or complete unemployment during the year. In this article an analysis[2] is made of the compensation engineers received solely for professional services during periods of employment, based on the monthly rates of earnings reported for all kinds of engineering work combined.

As in the previous analyses of earned annual incomes, it has been necessary to assume that the kind of engineering employment reported for the end of the year was the source of the income for that year.

**Table I. Comparison of 5 Levels of Monthly Engineering Earnings for All Professional Engineers Reporting in 1929, 1932, and 1934**

Figures derived from adjusted data as explained on this page, and without regard to kind of engineering employment reported or type of education

| Per Cent at Specific Earning Level | Monthly Engineering Earnings of More Than Specified Amount | | | Amount of Decrease | | | Per Cent of Decrease | | |
|---|---|---|---|---|---|---|---|---|---|
| | 1929 | 1932 | 1934 | 1929–34 | 1929–32 | 1932–34 | 1929–34 | 1929–32 | 1932–34 |
| 10 per cent | $609 | $484 | $435 | $174 | $125 | $49 | 28.6 | 20.5 | 10.1 |
| 25 per cent | 415 | 334 | 304 | 111 | 81 | 30 | 26.7 | 19.5 | 9.0 |
| 50 per cent | 289 | 235 | 210 | 79 | 54 | 25 | 27.3 | 18.7 | 10.6 |
| 75 per cent | 215 | 167 | 148 | 67 | 48 | 19 | 31.2 | 22.3 | 11.4 |
| 90 per cent | 162 | 123 | 112 | 50 | 39 | 11 | 30.9 | 24.1 | 8.9 |

## Monthly Engineering Earnings

Of the 33,852 engineers who reported as of December 31, 1929, that they were professionally active prior to 1930, 28,511, or 84 per cent, stated their average monthly rates for the engineering work in which they were engaged. These 1929 data, together with the adjusted[3] figures for 1932 and 1934, are shown in table I, without regard to age or kind of engineering employment reported.

As in the case of earned annual incomes, the range in the 1929 monthly engineering earnings of professional engineers was very great. While some 79 engineers reported earnings of less than $60 per month, 168 earned more than $1,880 a month. The median monthly earnings of the 28,511 reporting engineers was $289; one-quarter earned more than $415; and only 10 per cent had earnings greater than $609 a month. The lowest 25 per cent of the reporting engineers earned less than $215 a month while the lowest 10 per cent earned less than $162 a month.

Over the period 1929–34 the changes which occurred in monthly engineering earnings were similar to those previously noted in the discussion of earned annual incomes: (1) Earnings progressively declined from 1929 to 1934; (2) the sharpest absolute decreases occurred at the higher levels of earnings, but the greatest percentage decreases took place at the 2 lower income levels; (3) of the respective total decreases, almost two-thirds occurred between 1929 and 1932.

At all levels, however, the changes in monthly engineering earnings were very much less than those for earned annual incomes. This was due to the fact that annual earnings reflect the combined effects of several factors which were operative in the depression years: (1) The decline in engineering earnings; (2) the acute unemployment; (3) the deterioration in the nature of the available nonengineering work; and (4) the large influx of young engineers in the years 1930–34.

Clearly, earned annual income data cannot be used as a measure of the rates at which engineering services were purchased. Illustrative of this is the fact that in 1929 only at the 2 higher earnings levels did earned annual income exceed 12 times the monthly earnings reported solely from engineering services. In the years 1932 and 1934, the estimated annual earnings from engineering work only were greater at all 5 income levels. But while the lowest 10 per cent of the reporting engineers had earned annual incomes of not less than $872 in 1934, the monthly rate of earnings at this level shows a possible income of not less than $1,344 a year from engineering work.

More particularly, however, while the lowest 10 per cent of the reporting engineers engaged in engineering work in 1929 had earned not less than $162 per month, by 1934 the monthly earnings at this level were not less than $112. This was a decline of 30.9 per cent. By contrast, the earned annual incomes of a similar proportion of engineers had declined by 53.6 per cent. At the next highest income level, engineering earnings decreased by 31.2 per cent, as against 41.3 per cent in the case of earned annual incomes. Similarly, average monthly engineering earnings dropped by 27.3 per cent, whereas annual incomes declined by 33.0 per cent. This decline in the average earnings differed but little from those which occurred at the upper 10 and 25 per cent of the reporting engineers, namely, 28.6 and 26.7 per cent, respectively. The corresponding decreases in annual incomes of similar proportions of engineers were 31.2 and 31.6 per cent. In other words, while the range in the decline in engineering earnings was from 26.7 to 31.2 per cent, it was from 31.2 to 53.6 per cent for annual incomes.

The findings and comments of the preceding analysis

2. See "Engineering Income and Earnings, 1929–34," ELECTRICAL ENGINEERING for September 1937, pages 1089–1104, for details of the scope and methods of analysis.

3. The procedure of adjustment adopted was similar to that outlined in the "Employment in the Engineering Profession," 1929 to 1934, ELECTRICAL ENGINEERING, May 1937, pages 524–31. The numbers of younger engineers reporting in each income class for 1932 and 1934 were reduced in the ratio of 15 to 32 and added to the corresponding figures reported by the older engineers in 1932 and 1934.

also apply to the engineering earnings reported by the 5 professional classes. These are shown, also without regard to age[4] or kind of engineering employment, in table II.

In 1929, the upper 10 per cent of mining and metallurgical engineers, highest at this level, had earnings of not less than $792 per month as against $515 for civil engineers, who were lowest at this level. Second in order came chemical and ceramic engineers, of whom the upper 10 per cent had monthly earnings of not less than $732, followed by mechanical and industrial engineers, and electrical engineers, respectively, with not less than $674 and $587 a month. For the upper 25 per cent of the reporting engineers the order of the professional classes was the same, monthly earnings ranging from not less than $372 for civil engineers to not less than $503 a month for mining and metallurgical engineers. At the middle and 2 lower earnings levels, the differences in earning capacity were less marked. However, in each instance mining and metallurgical engineers and electrical engineers occupied the upper and lower extremes, respectively. Civil engineers shifted from fourth place at the average earnings level to second at the lowest earnings level, while chemical and ceramic engineers shifted from second to fourth place. The ranges in monthly earnings over these 3 levels were, respectively, from not less than $275 to $334, $201 to $241, and $148 to $186.

Despite the progressive declines in engineering earnings between 1929 and 1934, the orders of the professional classes at the 2 higher levels were essentially the same as those noted for 1929. However, at the middle earnings level, chemical and ceramic engineers had dropped from second place in 1929 and 1932 to fifth by 1934; but even in 1934 their monthly engineering earnings were practically the same as those of the civil engineers, who were fourth in order. Mining and metallurgical engineers were highest both in 1932 and 1934. Thus in the latter year, while their median earnings were $241 a month, those of both mechanical and industrial engineers and electrical engineers were $215 a month.

At the lowest 25 per cent earnings level of the reporting engineers, the lowest and highest figures for 1932 and 1934 were again reported, respectively, by chemical and ceramic engineers and mining and metallurgical engineers. At the same level in 1934 the range was from not less than $131 for chemical and ceramic engineers to not less than $154 for mining and metallurgical engineers. This reduction in the range of earnings was more pronounced at the lowest earnings level both in 1932 and 1934, for while in the former year it was from not less than $116 to not less than $126, in the latter it was from not less than $101 to

**Table II. Comparison of 5 Levels of Monthly Engineering Earnings for All Engineers Reporting in Each Professional Class in 1929, 1932, and 1934**

Figures derived from adjusted data as explained on page 1451, and without regard to kind of engineering employment reported or type of education

| Per Cent of Professional Class at Specified Earning Level[1] | Monthly Engineering Earnings of More Than Specified Amount | | | Amount of Decrease | | | Per Cent of Decrease | | |

| 75 per cent: | | | | | | | | | |
| Mining and metallurgical | 241 | 183 | 154 | 87 | 58 | 29 | 36.1 | 24.1 | 15.8 |
| Mechanical and industrial | 225 | 166 | 145 | 80 | 59 | 21 | 35.6 | 26.2 | 12.7 |
| Chemical and ceramic | 221 | 157 | 131 | 90 | 64 | 26 | 40.7 | 29.0 | 16.6 |
| Civil, agricultural, and architectural | 213 | 169 | 150 | 63 | 44 | 19 | 29.6 | 20.7 | 11.2 |
| Electrical | 201 | 163 | 148 | 53 | 38 | 15 | 26.4 | 18.9 | 9.2 |
| 90 per cent: | | | | | | | | | |
| Mining and metallurgical | 186 | 125 | 115 | 71 | 61 | 10 | 38.2 | 32.8 | 8.0 |
| Civil, agricultural, and architectural | 167 | 126 | 120 | 47 | 41 | 6 | 28.1 | 24.6 | 4.8 |
| Mechanical and industrial | 167 | 122 | 107 | 60 | 45 | 15 | 35.9 | 26.9 | 12.3 |
| Chemical and ceramic | 156 | 116 | 101 | 55 | 40 | 15 | 35.3 | 25.6 | 12.9 |
| Electrical | 148 | 123 | 108 | 40 | 25 | 15 | 27.0 | 16.9 | 12.2 |

1. Arranged in ascension of monthly engineering earnings for 1929.

4. It is important to note that any data concerning the several professional classes as a whole without regard to age tend to obscure the effects of different age distributions within the classes. Those classes with a relatively high proportion of older men for this reason are likely to show relatively high earnings, and those with relatively more younger men to show smaller earnings.

## Table III. Comparison of 5 Levels of Monthly Engineering Earnings, on Age Basis, for All Engineers Reporting in 1929, 1932, and 1934

Without regard to kind of engineering employment reported or type of education

| Age | Year of Graduation | Years After Graduation | Proportion With Monthly Engineering Earnings of More Than Specified Amount | | | | |
|---|---|---|---|---|---|---|---|
| | | | 10 Per Cent | 25 Per Cent | 50 Per Cent | 75 Per Cent | 90 Per Cent |
| **1929** | | | | | | | |
| 64 years and over | Prior to 1889 | 40 and over | $820 | $601 | $388 | $263 | $194 |
| 56–63 years | 1889–96 | 33–40 | 1,050 | 628 | 425 | 296 | 210 |

| 27 years | 1930 | 4 | 199 | 172 | 148 | 125 | 104 |
| 26 years | 1931 | 3 | 182 | 156 | 137 | 114 | 94 |
| 25 years | 1932 | 2 | 169 | 145 | 124 | 103 | 84 |
| 24 years | 1933 | 1 | 159 | 138 | 116 | 98 | 82 |
| 23 years | 1934 | 0 | 149 | 129 | 110 | 91 | 75 |

not less than $120, the upper and lower extremes being reported, respectively, by the civil engineers and the chemical and ceramic engineers.

The decline in engineering earnings of each professional class was very much less than that which occurred in earned annual incomes. The greatest percentage decreases took place at the 2 lower levels. For example, while engineering earnings of electrical engineers at these limits declined by 26.4 and 27.0 per cent, the corresponding annual incomes decreased by 42.6 and 56.0 per cent. In the case of chemical and ceramic engineers, the drops in earnings at these levels were 40.7 and 35.3 per cent as against 52.2 and 63.8 per cent in their annual incomes.

### Monthly Engineering Earnings Related to Age

In table III there are presented the monthly engineering earnings, by age,[5] of all engineers combined and without regard to kind of engineering employment.

As shown in table III there was, in general, a steady advance in monthly earnings at all levels up to the highest age groups. Except for the absence of the exceptionally rapid rise from 23 to 25 years, the changes with age in monthly engineering earnings at all 5 levels show no marked differences from those derived from the analysis of earned annual incomes by age. Thus, in 1929 the compensation for engineering services of the lowest tenth of the reporting engineers steadily increased from over $115 a month for those 23 years to a maximum of over $232 a month for those who were between 48 and 55 years. At each of the 4 higher earning levels maximum earnings were reached some 8 years later, or near to age 60. The respective maxima were not less than $297, $414, $592, and $1,050 per month. Even for engineers 23 years of age there was a considerable spread in earnings. This is evidenced by the fact that at the average level the earnings were not less than $149 a month, above this one-quarter earned over $174, and one-tenth over $215 per month, as against monthly engineering earnings of over $130 and $115 at the two lower levels.

The spread in engineering earnings with advancing age became quite marked at the age of 30; that is, some 8

5. Throughout the ensuing discussion age and years after graduation are used interchangeably. Of course in the case of nongraduates (that is "other engineers") age only applies. The relationship between these 2 factors can readily be derived from the fact that the median age of graduation of new graduates to the profession was found to be 23 years.

## Table IV. Comparison of 5 Levels of Monthly Engineering Earnings on Age Basis for All Graduate Engineers Reporting in 1929, 1932, and 1934

Without regard to kind of engineering employment reported or type of education

| Age | Year of Graduation | Years After Graduation | Proportion With Monthly Engineering Earnings of More Than Specified Amount | | | | |
|---|---|---|---|---|---|---|---|
| | | | 10 Per Cent | 25 Per Cent | 50 Per Cent | 75 Per Cent | 90 Per Cent |
| **1929** | | | | | | | |
| 64 years and over | Prior to 1889 | 41 and over | $880 | $624 | $417 | $302 | $215 |
| 56–63 years | 1889–96 | 33–40 | 1,152 | 661 | 472 | 326 | 243 |
| 48–55 years | 1897–1904 | 25–32 | 1,018 | 625 | 434 | 319 | 252 |
| 40–47 years | 1905–12 | 17–24 | 826 | 552 | 410 | 306 | 245 |
| 36–39 years | 1913–16 | 13–16 | 663 | 490 | 356 | 286 | 231 |

| 25 years | 1932 | 2 | 169 | 145 | 124 | 102 | 84 |
| 24 years | 1933 | 1 | 159 | 137 | 116 | 98 | 82 |
| 23 years | 1934 | 0 | 149 | 129 | 109 | 91 | 75 |

years earlier than was the case for earned annual incomes. (See figure 1.) Again the earnings of the upper 10 per cent of reporting engineers diverged sharply from those at corresponding ages in the lower levels. Thus, at age 44 the former were greater than the average by some 102 per cent, as against a corresponding difference at the upper 25 per cent level of only 33 per cent. At age 60, the respective differences were 144 and 48 per cent.

These general relationships of monthly engineering earnings by age of all engineers[6] reporting also held in the years 1932 and 1934, as well as for the monthly earnings of all graduates[7] shown in table IV.

Consideration will now be given to the extent to which monthly engineering earnings may have been affected by the depression. Reference, however, will be made only to the data reported by all graduate and "other" engineers combined.

For men of advancing years and experience, it appears from the data presented in table V that over the period 1929–34 only those engineers who were 23½ years in 1929 and 28½ in 1934 reported increased earnings. Earnings of the next higher age group showed practically no change. For succeeding age groups the declines in earnings were progressively greater. Thus, while there was a 15 per cent decrease between 1929 and 1934 at the middle level of earnings of engineers who were 30 in 1929 and 35 in 1934, the decrease was as high as 24 per cent for engineers who were 65 years of age in 1934. A similar situation existed at the other four earnings levels, for all engineers, and also for graduate engineers only, as shown in table VI.

One important aspect of these engineering earnings is that it is now possible to determine the compensation younger engineers received for their engineering services. This information could not be obtained from the data on earned annual incomes for reasons previously cited. The principal reason, however, was that most engineers 23 years of age could not have worked a full year.[8] Many of

6. That is, graduates and "other" engineers combined.

7. That is, postgraduates, nonengineering graduates, and first-degree engineering graduates combined.

8. This qualification applies only to graduate engineers, for in the case of "other" engineers many of them could have been working for a year or more.

the graduates estimated what their annual earnings would have been, based on what they had earned for the first 6 months after graduation. Obviously, this necessity for estimating does not apply to the monthly earnings for engineering work. Hence, the monthly earnings data are the most accurate indication of what the rates of compensation of younger engineers were for engineering work. This situation is best exemplified by considering the earnings reported by men who were of identical ages in 1929, 1932, and 1934, as presented in tables VII and VIII.

These data reveal the fact that the newcomers to the profession suffered less than those with from 2 to 5 years' experience in engineering. Thus, while median monthly earnings of the newcomers were 26 per cent less in 1934 than those of men of similar ages in 1929, they were 34 per cent less in the case of men with from 2 to 5 years' experience in each of these years. But it will also be noted that the declines in earnings of engineers between 1929 and 1934 with from 20 to 37 years of experience were practically the same as those reported by engineers $23^1/_2$ years of age. Furthermore, a similar relationship existed at the 4 other earnings levels, despite the fact that the declines in earnings were relatively greater in the case of engineers at the 2 lower earnings levels.

It will be recalled that in the discussion of employment status that as far as available engineering work was concerned, the tendency appeared to be to give preference to engineers who entered the profession in the period 1930–34. The analysis of the data in the table VII shows that it was not those engineers who entered the profession in 1934 who suffered relatively the greatest cuts but those who had entered during one or other of the depression years, 1930–33, inclusive. Similarly, data for earnings of graduates of identical ages are shown in table VIII.

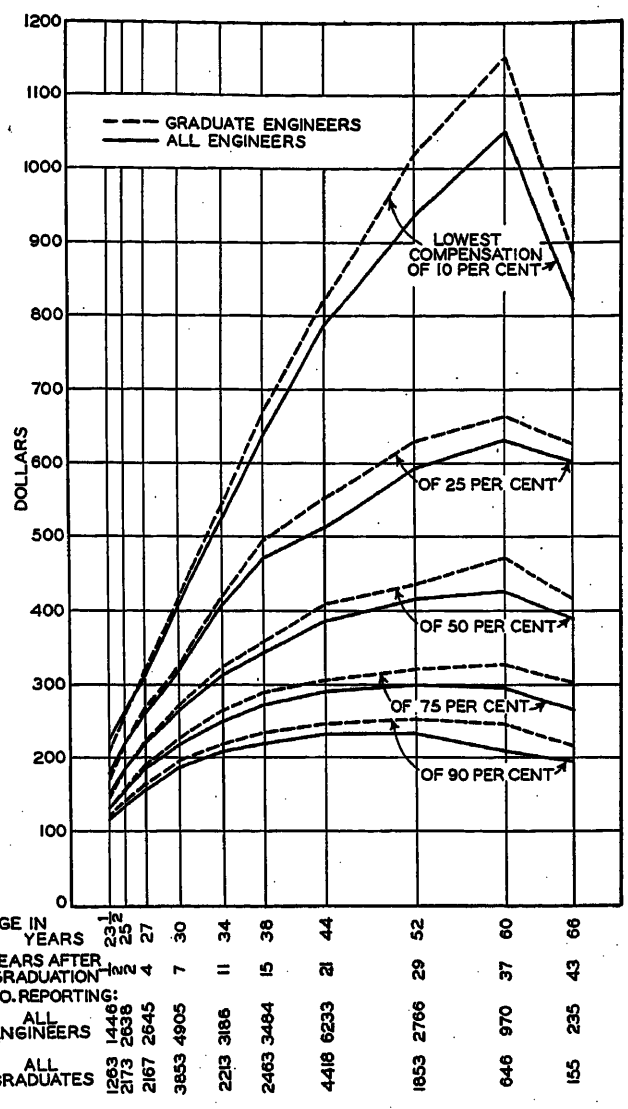

**Figure 1. Chart of monthly compensation of professional engineers in engineering work by age in 1929**

Includes compensation for all kinds of engineering services studied

## Engineering Earnings and Education

Of all engineers who furnished information on the monthly rates of compensation received by them for engi-

1. Includes those engineers who were professionally active prior to 1930.

neering services in 1929, 21,205 were graduates and 7,305 were "other" engineers. The former number represented 86 per cent of the 24,837 graduates, and the latter covered 81 per cent of the 9,015 "other" engineers who reported that they were professionally active prior to 1930. A comparison of the engineering earnings of these 2 groups is shown, without regard to age and kind of engineering employment reported, in table IX.

Although the figures in the third from the last column in table IX indicate an advantage in favor of those men who have engineering degrees, this advantage is less clearly defined than was indicated in the similar analysis of earned annual incomes. This is evidenced by the fact that only at the highest earnings level did the earnings of graduates of all 5 professional classes exceed those of "other" engineers. Even at this level, the advantage did not accrue in equal measure for each of the 5 professional classes.

Thus, while the monthly earnings of the upper one-tenth of the mining and metallurgical graduates exceeded those of the upper tenth of the "other" engineers by $94 a month, the differences in monthly engineering earnings among the 4 remaining professional classes ranged from $31 for mechanical and industrial engineers to $61 for chemical and ceramic engineers. At the upper 25 per cent level, the engineering earnings of mechanical and industrial graduates and "other" engineers were practically the same. There was a difference of only $13 between the earnings of the 2 groups in the case of mining and metallurgical engineers, and for electrical engineers the difference was only

| Electrical | 199 | 187 | 187 | 206 | 179 | 168 | 104 | 96 | 90 |
| **90 per cent:** | | | | | | | | | |
| Mining and metallurgical | 185 | 142 | 145 | 195 | 132 | 135 | 105 | 93 | 93 |
| Civil, agricultural, and architectural | 169 | 143 | 140 | 164 | 131 | 128 | 97 | 92 | 91 |
| Mechanical and industrial | 160 | 138 | 136 | 192 | 134 | 125 | 120 | 97 | 92 |
| Chemical and ceramic | 156 | 150 | 146 | 154 | 121 | 129 | 99 | 81 | 89 |
| Electrical | 145 | 145 | 144 | 159 | 128 | 126 | 110 | 89 | 88 |

1. Includes all engineers who reported they were professionally active prior to 1930.
2. Arranged in ascension of graduate monthly engineering earnings for 1929.
3. Graduate engineers embrace all postgraduates, nonengineering graduates, and final-degree engineering graduates.
4. "Other" engineers embrace all engineers with college course incomplete, noncollegiate technical school course, and secondary school education.

$22 a month. However, at this level, in the case of chemical and ceramic engineers and civil engineers the differences were much higher, being $61 and $62 per month, respectively.

At these 2 earnings levels, the relationships between the earnings of graduates and "other" engineers in 1932 and 1934 were similar to those just noted for 1929.

At the average and at the 2 lower levels of earnings, the ratios of engineering earnings of the 2 groups of engineers were practically the same as those noted for earned an-

nual incomes. That is, in 1929 there was a slight advantage in favor of the "other" engineers, which was maintained to a somewhat greater degree in 1932 and 1934 than was the case for earned annual incomes. In part, however, this advantage in earnings of "other" engineers was due primarily to a higher age among the nongraduates in the groups compared.

The advantages in increased earning capacity accruing from formal education are better seen in table X, which shows the engineering earnings by type of education and by age. Only the median earnings are given, as insufficient data were obtained for the 2 lower and the 2 higher earnings levels to enable a complete comparison for all age groups and types of education.

The extra years of experience which the "other" engineers had while the graduates were in school permitted of their obtaining higher earnings than graduates only up to a point corresponding to 5 years after graduation. Even at 2 years after graduation in 1929 the differentials in earnings between the 2 groups were slight. Thus, while the median monthly earnings of "other" engineers ranged from $183 for secondary-school engineers to $193 for mechanical engineers whose college course was incomplete, the earnings of graduates from engineering work ranged from $166 per month for those with a nonengineering education to $187 for first-degree civil engineers. At 4 years after graduation, as will be seen from figure 2, the graduates were beginning to pull ahead of the "other" engineers.

## Table X. Median Monthly Engineering Earnings in 1929, 1932, and 1934, for All Engineers Reporting by Age and Type of Education

Without regard to kind of engineering employment reported

| Age | Year of Graduation | Years After Graduation | Postgraduates | Nonengineering Graduates | First-Degree Engineering Graduates | | | | | Others With— | | | | Secondary-School Education |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | Chemical and Ceramic | Civil, Agricultural, and Architectural | Electrical | Mechanical and Industrial | Mining and Metallurgical | College Course Incomplete: Civil, Agricultural, and Architectural | College Course Incomplete: Mechanical and All Others | Noncollegiate Technical Course: Civil, Agricultural, and Architectural | Noncollegiate Technical Course: Mechanical and All Others | |
| **1929 Earnings (in Dollars)** | | | | | | | | | | | | | | |

1. Fewer than 10 engineers reported.
2. Includes chemical, ceramic, electrical, industrial, mining, and metallurgical engineers.

Thus, while the range in the median monthly earnings of the former was from $225 for first-degree electrical engineers to $250 a month for first-degree chemical and ceramic engineers, it was from $200 for engineers with secondary-school education to $229 a month for mechanical and industrial engineers with incomplete college courses in the case of the "other" engineers. Beginning at 5 years after graduation, the effect of a formal education on engineering earnings was accentuated. For example, at 11 years after graduation, the average monthly earnings of first-degree civil engineers were greater than those of the "other" engineers of this professional class. The median monthly earnings were $305 for graduates, $257 for those whose college courses were incomplete, and $254 for civil engineers who had attended noncollegiate technical schools. Similarly, in the case of first-degree electrical engineers and mechanical and industrial engineers, earnings were greater than those reported by the members of these professional classes whose college courses were incomplete or who had attended noncollegiate technical schools.[9]

It will also be noted that while mechanical engineers with incomplete college courses had the highest earnings of any of the groups of "other" engineers, their earnings differed very little from those of first-degree civil engineers. Thus, at 11 years after graduation the latter reported median earnings of $305 a month as against $319 a month for mechanical engineers with incomplete college courses. The corresponding figures at 29 years after graduation were $407 and $423 a month.

Furthermore, from 5 to 37 years after graduation, there was a fairly uniform relationship in the ranking of the earnings reported by the several types of education. Relatively, this uniformity was most marked among the "other" engineers. Thus, while secondary-school engineers remained tenth in order, civil engineers whose college courses were incomplete, or who had attended noncollegiate technical schools, held respectively eleventh and twelfth places. Over the same period, first-degree chemical and ceramic engineers were first in order. They did, however, rank tenth at 2 years after graduation. Among the remaining types of education such shifts as did occur were not very pronounced. Even in 1934, the same relative positions were maintained.

With advancing age, the 1929 data show that there was a considerable advantage in engineering earnings in favor of the graduates. Thus, between civil engineers who had

9. The term, "mechanical and all others" shown in table IX under "college course incomplete" and "noncollegiate technical schools" includes chemical and ceramic, electrical, industrial, and mining and metallurgical engineers.

first degrees and those who had incomplete college courses, the differences for men 23, 33, 43, 53, and 60 years of age were \$24, \$45, \$55, \$93, and \$109 a month, while between those with first degrees and noncollegiate technical school educations, the corresponding differences were \$20, \$48, \$65, \$118, and \$77 a month.

There was also a distinct variation in the earning capacities among both graduate and "other" engineers. Thus, at 10 years after graduation, the 1929 median monthly engineering earnings of graduates ranged from \$290 for civil engineers to \$368 for chemical and ceramic engineers. Graduates' median earnings 30 years after graduation ranged from \$408 for civil engineers to \$492 in the case of chemical and ceramic engineers. For "other" engineers, the range in earnings of men whose age corresponded to 10 years after graduation, that is, 33 years was from \$242 to \$300 a month, and at 53 years of age, or corresponding to 30 years after graduation, the range was from \$290 to \$422 a month. At both of these age points, the lowest earnings among "other" engineers were reported by noncollegiate technical-school civil engineers, the highest by mechanical and industrial engineers with incomplete college education.

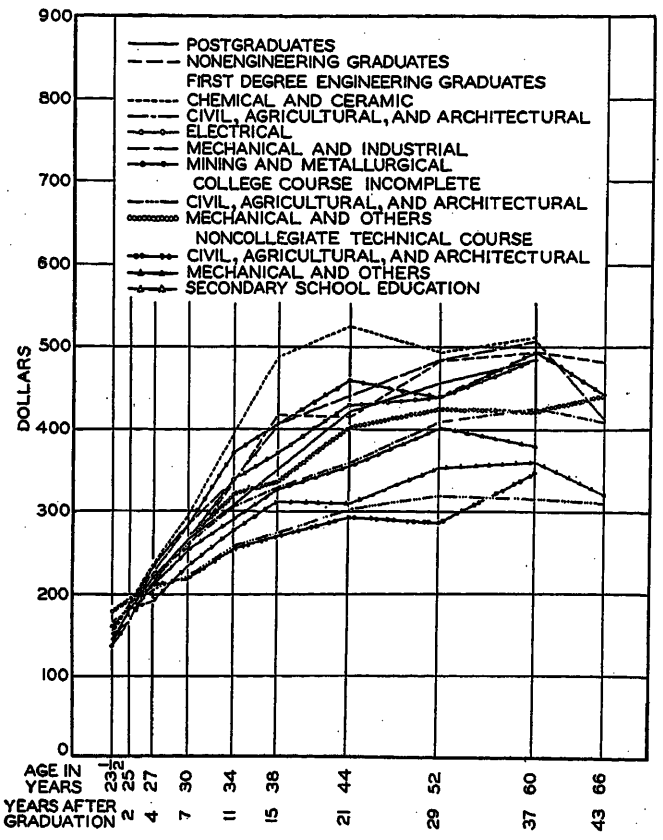

**Figure 2. Comparison of medians of monthly rate of compensation according to age, 1929**

Includes compensation for all kinds of engineering services reported

A further advantage of formal engineering education was that graduate earnings from engineering work continued to increase for several years beyond the point of maximum earnings of "other" engineers. The earnings of the latter either remained stable or declined at 53 years of age.

Consideration will now be given to the effect of the depression on earnings of men with advancing years and experience and different educational backgrounds.

Over the period 1929–34, the data in table XI indicate that the graduates who were $23\frac{1}{2}$ years in 1929 and $28\frac{1}{2}$ years in 1934 received increased earnings for all kinds of engineering, except in the case of mining and metallurgical. There were, however, no increases reported by any of the "other" engineers of corresponding ages. By contrast, for the selected age groups of 52 to 57 and 44 to 49 years, decreases in earnings occurred among both graduate and "other" engineers in almost equal measure. For example, for engineers who were 44 years in 1929 and 49 in 1934, the earnings of the graduates declined from 19 to 24 per cent, while those of the "other" engineers fell by 18 to 25 per cent.

On the other hand, for men with identical years of experience, the earnings received in 1934 by both graduates and "other" engineers were all less than those which were obtained in 1929. Thus, in table XII it will be noted that at 2 years after graduation the earnings obtained for engineering services in 1934 were less than those received in 1929 by from 32 to 41 per cent for all types of education, except nonengineering graduates and those engineers with a secondary-school education. In the case of nonengineering graduates, the earnings were 24 per cent less and for engineers with secondary-school educations they were 29 per cent less.

Again it will be noted that the decreases reported by men with 5 years' experience were, in general, greater than those for men who had had but 2 years' experience and also greater than the declines in earnings reported for men with from 10 to 37 years' experience.

**Table XII. Percentage Decreases in Median Monthly Engineering Earnings Over Period 1929–34 for Corresponding Years After Graduation, by Type of Education**

Without regard to kind of engineering employment reported

| Type of Education | Per Cent of Decrease in Earnings at Specified Years After Graduation | | | | | |
|---|---|---|---|---|---|---|
| | 2 | 5 | 10 | 20 | 30 | 37 |
| Postgraduates | 32 | 34 | 24 | 26 | 21 | 21 |
| Nonengineering graduates | 24 | 33 | 30 | [1]8 | 23 | 23 |
| First degree engineering graduates: | | | | | | |
| Chemical and ceramic | 34 | 36 | 33 | 31 | 14 | [2] |
| Civil, agricultural, and architectural | 32 | 32 | 30 | 25 | 29 | 27 |
| Electrical | 34 | 33 | 31 | 20 | 18 | 19 |
| Mechanical and industrial | 39 | 35 | 32 | [1]10 | 30 | 30 |
| Mining and metallurgical | 37 | 42 | 37 | 32 | 22 | 27 |
| College course incomplete: | | | | | | |
| Civil, agricultural, and architectural | 33 | 30 | 31 | 26 | 24 | 21 |
| Mechanical and others[3] | 34 | 37 | 36 | 34 | 27 | 25 |
| Noncollegiate technical course: | | | | | | |
| Civil, agricultural, and architectural | 41 | 26 | 31 | 27 | 23 | 33 |
| Mechanical and Others[3] | 36 | 37 | 34 | 29 | 31 | 24 |
| Secondary-school education | 29 | 28 | 34 | 18 | 23 | 19 |

1. Despite the fact that at 20 years after graduation, nonengineering graduates and mechanical and industrial engineers show only 8- and 10-per cent decreases in earnings, the consistency of the remaining decreases shown is too regular for these particular differences to have any effect on the general argument.
2. Fewer than 10 engineers reported.
3. Includes chemical, ceramic, electrical, industrial, mining, and metallurgical engineers.

# Modern Trolley-Coach Operation

By EDWARD DANA

THE BOSTON Elevated Railway serves a population of about 1,531,000 people, distributed over an area of 111.56 square miles and segregated in 14 municipalities, including both towns and cities. Within its territory the railway supplies practically all of the public transportation, except taxicabs. The backbone of its system is formed by its rapid-transit division, with elevated lines, subways and some leased surface right-of-way. The rapid-transit lines are confined to Boston and Cambridge.

The territory is covered with a network of surface-car lines, with motor-bus lines and, recently, with a few trackless-trolley lines. These surface lines serve partly as feeders for the rapid transit and partly to meet local service demands.

The fare with transfers to and from the rapid-transit lines is 10 cents; that for local riding on surface lines is 5 cents. About 30 per cent of the riders pay the lower fare.

Such a unified system of local transportation as that of the Boston Elevated provides an unusual opportunity for adapting each type of service to the best advantage within certain limitations. The expensive subways and elevated structures in fixed locations, however, provide little flexibility. They are dependent largely upon the surface railways, trackless trolleys, and motor buses as feeders.

The surface railway situation in Boston is unusual, in fact is unique, in that in and even beyond the congested business section the cars run through subways and on overhead structure, which make them to this extent a part of the rapid-transit system, with which these structures connect.

While the surface subways and viaduct expedite the movement of surface cars, they also decrease the flexibility of the surface lines. It is probable that the use of subways for surface cars is a temporary expedient in urban transportation, the logical use of such expensive way and structure being for rapid transit.

The shifting demand for urban and suburban transportation in a group of communities like metropolitan Boston renders necessary a ready adaptability of services. Thus in spite of heavy investment in track and overhead construction, it has been necessary to abandon many miles of surface railway when the demand for service was greatly reduced, or when the track was wearing out and the density of traffic would not warrant rebuilding.

The motor bus and, later, the trackless trolley entered the picture at the time when something was urgently needed to meet this situation. The Boston Elevated began to use the motor bus in 1922 and in replacing uneconomical rail lines or in giving modern transportation to communities not previously adequately served increased its bus mileage from 63,959 revenue-miles in 1922 to 10,485,554 revenue-miles in 1936. At the same time the surface-car mileage fell from 37,195,035 revenue-miles in 1922 to 24,254,263 revenue-miles in 1936. The combined mileages of the 2 services show a reduction from 37,258,994 revenue-miles in 1922 to 34,739,817 in 1936, or about 6.8 per cent.

The experience of the Boston Elevated Railway with the trackless trolley has to date been on a small scale and extends back only to April 11, 1936, when a car line in Cambridge was replaced by a trackless-trolley line. Since this line was opened the weather has been favorable so that neither on it, or a line started early in 1937, has there been opportunity to observe operation under conditions such as prevailed during parts of the two preceding winters. The railway has now 49 vehicles in operation.

The Cambridge line serves the Harvard square business district, and residential and business districts of East Cambridge. The terminals are important interchange points for car lines from Boston and for local radiating car and bus lines.

The Cambridge trackless-trolley route is 2.6 miles long, one-way mileage, requires 10 trackless trolleys and furnishes a headway of 5 to 6 minutes in rush hours and 12 minutes out of the rush hours. It replaced a car line.

In another part of the elevated territory, in Malden and Everett, 3 trackless-trolley lines have been installed during 1937, all terminating at one end in the main elevated-line terminal in Everett.

One of these, the Linden line, connects the terminal with an outlying residential section of Malden, and serves also certain business sections of Everett. The Linden line is 3.6 miles long, requires normally 13 vehicles, and gives a 5 to 6-minute time in rush hours and a 15-minute normal time headway. It replaced in part a car line and in part a bus line.

The second Everett line connects the rapid-transit terminal and an important cemetery, which gives the line its name, Woodlawn. The Woodlawn line connects the business section with several residential districts. It is 2.6 miles long, partly over the Linden line route, requires 11 vehicles, and operates on a 3- to 4-minute headway in rush hours, and a 12- to 15-minute headway at other hours. This route replaced a car line.

The third Everett trackless-trolley route operates out of the rapid-transit terminal and connects it with Malden square, 3 miles away by trackless-trolley route. Part of the route is over the Linden line. Here the rush-hour headway is from 5 to 6 minutes and the normal headway is 15 minutes. Seven vehicles are required for this service. The 3 Everett lines operate from the same carhouse

A paper recommended for publication by the AIEE committee on transportation. Manuscript submitted October 7, 1937; released for publication October 15, 1937.

EDWARD DANA is president and general manager of the Boston (Mass.) Elevated Railway Company.

where 8 additional trackless trolleys are available as "spares."

Other lines are in the preparatory stages as this is written, all designed primarily to serve as feeders for the rail lines and to furnish attractive local service also. The fares on the lines mentioned, without transfer to the rapid-transit lines, is 5 cents. The base fare in Boston, as stated, is 10 cents. In elaboration of the above expression "in the preparatory stages," following is the procedure locally.

**Trackless Trolley Lines of Boston Elevated Railway**

| Name of Line | Length of Route in Miles | Number of Vehicles for Regular Requirements | Spare Vehicles | Headway Rush-Hour | Headway Normal | Date Service Was Inaugurated |
|---|---|---|---|---|---|---|
| Harvard-Lechmere (Cambridge) | 2.6 | 7 | 3 | 5 to 6 minutes | 12 minutes | April 11, 1936 |
| Linden-Everett Terminal (Malden and Everett)* | 3.6 | 13 | 8 | 5 to 6 minutes | 15 minutes | January 9, 1937** |
| Woodlawn-Everett Terminal (Everett)* | 2.6 | 11 | 8 | 3 to 4 minutes | 12 to 15 min. | June 19, 1937 |
| Malden Square-Everett Terminal (Malden and Everett)* | 3.0 | 7 | | 5 to 6 minutes | 15 minutes | September 11, 1937 |

* These routes overlap to some extent. Total length of street traversed, 7.8 miles
** Part of this line began operation November 28, 1936

Prior to the inauguration of a new trackless-trolley line it is necessary to secure a permit covering the route from the city and town authorities within whose jurisdiction the route will lie, together with a location for the necessary poles, wires, and other appliances and apparatus. Before the granting of such a permit, it is necessary that a public hearing be held, notice of which must be published in one or more newspapers at least 14 days prior to date set for hearing. The granting of this permit must then be approved by the State Department of Public Utilities, after advertising public hearings. After the poles and all the overhead construction have been erected and installed, it is then necessary to secure a certificate of safe operation from the Department of Public Utilities.

Trackless trolleys have practically the same status as street cars in Massachusetts and are exempt from the requirements of the motor-vehicle law. In securing the necessary legal authority incidental to the operation of trackless trolleys, the procedure followed is that contained in the law governing street-railway locations.

The adoption of a new form of transportation, even one only so moderately novel as the trackless trolley, and its integration in a composite system, cannot be decided wholly from theoretical considerations. If a transportation system were being laid out as a new proposition, there would be much more freedom than exists in a situation like that of Boston.

The management of the Boston Elevated followed with interest the experiments with the modern trackless trolley beginning in Salt Lake City, in 1928, and early made plans for trying out the vehicle locally.

Extensive experience with the motor bus had demonstrated the advantages of an independent unit for existing rail routes on which the traffic had shrunk to or below the minimum at which car service is profitable, especially where the track needed replacing. The motor bus proved useful also in feeling out the traffic possibilities of a proposed route.

The trackless trolley occupies a place between the trolley car and the bus. It is really a trolley car which does not require tracks. It operates noiselessly as contrasted with the car and without fumes as contrasted with the bus. In common with the bus and in contrast with the car it permits curb loading eliminating the risk involved in crossing traffic before boarding and after alighting.

The trackless-trolley vehicle body is limited in size by street conditions. It probably will never be possible to build this vehicle with the capacity of a car running on rails. If a large number of people require service within limited periods, large vehicles are necessary. Trolley cars on rails are best for heavy peak loads, but where they have been ruled out on the basis of investment and operating cost, the large-body trackless trolley vehicle is next best.

Early trackless-trolley bodies were kept within bus size limits; but for use in cities with wide streets, vehicles wider than the early 96 inches were found practicable. Some designs went to 106 inches. The wider bodies make wider aisles possible and decrease the time required for passengers to board and alight.

In Boston a 100-inch width is used, as the probable maximum width for local street layouts.

The permissible length depends also on street conditions, particularly at intersections. A body with seating capacity for 40 persons is a popular size, the length being say around 33 to 34 feet. This compares with a length of 6 to 8 feet less for the 30-passenger trackless trolley, also a popular size and used where traffic demands do not warrant the larger vehicle.

As far as general design, seating, lighting, and other items the trackless trolley body utilizes the progress which has been made in the development of the comfortable and attractive bus body of today.

From the operating standpoint, the high acceleration rates and smooth pick-up of the trackless trolley permit it to make good speed amid vehicular traffic. This results from the large power capacity of the vehicle, from the characteristics of the series motor, which gives maximum torque at starting, and from the ease of control of the starting current by means of rheostats graduated in small steps. With these vehicles, the driver finds himself limited as to speed by his environment rather than the capacity of his equipment.

The pedal control here, as in the gasoline motor bus, greatly facilitates smooth operation, as compared with the trolley car, besides leaving the operator's hand free for other work. The absence of gear shift and clutch in the trackless trolley accentuates this advantage.

The replacement of trolley cars by gasoline-motor buses on a large scale is a serious matter from the power standpoint to railways that generate their own power. This is

the situation in Boston, where the Railway has 2 up-to-date power plants, one having an installed generator capacity of 120,000 kilowatts, the other of 60,000 kilowatts. There is an equally modern distribution system at 13,200 volts, 3-phase, with automatic supervisory control in several substations.

The trackless trolley tends to offset this power load loss, and the low power cost under these conditions is an argument in its favor.

The trackless trolley comes into prominence at a time when its designers can profit from experience gained in the development stages of other vehicles. In an earlier era of this development, when the trackless trolley was given a fair trial on Staten Island, N. Y., in Rochester, N. Y., and elsewhere it antedated the modern motor bus. The vehicle was a small car body mounted on a truck chassis with solid rubber-tired wheels. It proved not to be a formidable competitor of street railways, partly because it had little in the way of comfort and speed to offer the passenger, and partly because the trolley car enjoyed a high degree of popularity.

Since then the modern gasoline motor bus has been evolved, a distinctive vehicle, profiting of course by the marvelous development of the automobile. The pneumatic tire must be credited with a large share in the present-day status of the motor bus, and in turn of the trackless trolley. Not only tires, but bodies, steering gear, control and braking systems form the contributions of the motor bus to trackless trolley development.

Still closer approach to the trackless trolley was the gas-electric bus, for this, among other things, forced the development of the light-weight series motor. It is a short step from the gas-electric bus to the trackless trolley, in fact in one type of trackless trolley it is no step at all, that is in the so-called "all-service" vehicle used on a large scale by the Public Service Coordinated Transport. This vehicle is driven by an electric motor which uses central power station energy where wires are available and uses a gasoline or Diesel engine to generate power where wires are not available.

The trackless trolley undoubtedly owes something also to the research work done by the American Transit Association in developing the so-called "P.C.C." (Presidents' Conference Committee) car. This research extended to all of the elements of a modern rail car, many of which are found in the trackless trolley.

While undoubtedly the trackless trolley utilized developments in other vehicles, it in its turn has furnished incentive for further development of the high-speed light-weight motor. Motors of 125 horsepower are now in use in these equipments on 40-passenger trolley coaches, with a weight per motor of not much over 1,100 pounds. The combined weight of 2 65-horsepower motors, generally used on 2-motor equipments is several hundred pounds greater. The single-motor equipment also makes possible a saving in the weight of the control apparatus.

Most of the trackless-trolley equipments recently ordered are single-motor equipments. Lower cost, less weight, and simplicity are the ruling considerations, offsetting the higher energy consumption due to necessary abandonment of the series-parallel control which is standard on all d-c traction equipment.

In some ways the use of rheostatic control in the trackless trolley seems like a technical step backward. It took a long time to develop and perfect the series-parallel method of bringing a vehicle to speed, a method which is relatively economical. On the other hand the power item is not relatively as important as it once was. Modern power plants produce electrical energy at a much lower cost than formerly, whereas other items of transportation cost have gone up.

Again, the simplicity and smoothness of the rheostatic control offsets power costs. A great deal depends upon the skill of the operator as to the waste of power in the rheostats. A new technique must be learned, to prevent unnecessary running on resistance points.

The shunted field is an important feature of the single-motor equipment, which tends to improve operating efficiency and give better speed control. The design is such as to give a better free running speed and acceleration with one motor than with 2, and to permit better schedule performance.

The advantages of the single-motor equipment are so appealing that only the lack of availability of a suitable axle delayed its adoption on the 40-passenger trackless trolleys, although it was used earlier in the 30-passenger vehicle, where a suitable axle for a single 65-horsepower motor was available.

In the past, salient obstacles to the adoption of the trackless trolley have been the necessity for using 2 trolley wires and trolley poles, and the requirement that the mounting pole be sufficiently flexible to permit curb loading and passing of other traffic. Operating and construction difficulties connected with the double trolley have been overcome and with careful design the overhead need not be unsightly. Overhead intersections and switching involve complications but improvement in line equipment has kept pace with the vehicle. The double trolley is not the bugaboo that it once was.

The suddenness with which the trackless trolley has been accepted as a piece of rolling-stock in good standing is remarkable. It was not until 1935 that the number of vehicles in use was large enough to attract much attention. From 1928 to 1935 there was an average increase around 70 vehicles per year. The next year the number nearly doubled and as this is written there are more than 1,600 vehicles in service or on order, including the "all service" vehicles of Public Service.

There appears to be a growing tendency to order trackless trolley for service of medium density where moderate headways are required, leaving the extremes in both directions for the trolley car and the motor bus, respectively.

In all communities served by a public utility the patrons and the public are impressed by indications of progressiveness on the part of the utility. The addition of the trackless trolley to older equipment has a public-relations value in this direction. In the many cities where trackless trolleys have been recently adopted, an encouraging public appreciation has rewarded the management.

# Switching Surges With Transformer Load-Ratio Control Contactors

By L. F. BLUME

## Introduction

THE INVESTIGATION described in this paper was undertaken to determine the magnitude and characteristics of the abnormal voltage transients accompanying the operation of load ratio control contactors on power transformers. As test results definitely established the fact that currents may be abruptly ruptured at other than normal current zero, accompanied by very severe over-voltages, the main purpose of the paper was directed to this phenomena, both from the experimental and theoretical viewpoint. It is believed that the subject will prove interesting to anyone concerned with switching surges in general, especially in view of the fact that certain aspects of the phenomena appear not to have been presented heretofore. Thus, the effect of current interruption at other than normal frequency current zero is gone into in detail; general equations on recurrent restriking are given; the extremely interesting possibility of restriking so as to practically discontinue the voltage transient is described; and the paradox of an increase in recovery voltage when shunt capacitance is increased is explained. These points are illustrated and supported by oscillographic evidence.

It should be noted, however, that in the experiments described, abrupt current rupture occurred only when values were 15 amperes or less, and were not obtained above 15 amperes. Furthermore, tests were limited to one type of circuit and to one type of switching device, namely, those used in connection with transformer tap changing equipments. Obviously the scope of the experiments is so limited that considerable caution must be used in forming general practical conclusions.

The now classical theory of circuit breaker recovery voltages, as first given by Park and Skeats[1] and subsequently extended by Boehne,[2] assumes that rupture of the current does not take place until a normal current zero. At this instant the current permanently extinguishes and the isolated part of the circuit, comprising the inductances of apparatus and the (small) capacitances of windings, bus bars, etc., undergoes a local oscillation. In a single frequency local circuit of this nature the oscillation results because the circuit capacitance is charged to the circuit voltage prevailing at the instant of normal current zero, and for a completely reactive circuit this is the normal

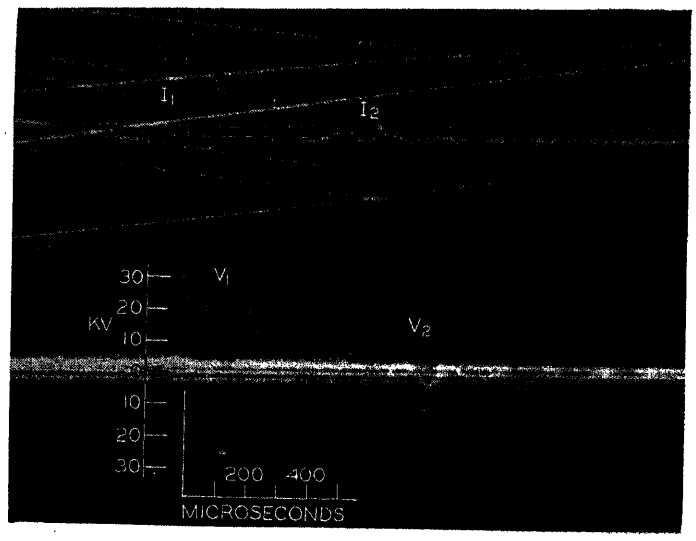

**Figure 2. Cathode-ray oscillograms of 2 switching transients**

frequency peak recovery voltage. It follows, then, that the transient oscillation has a maximum value not exceeding normal frequency peak recovery voltage; and the total voltage across the switch contacts, being the sum of the high frequency oscillation and the normal frequency voltage, cannot exceed double normal frequency recovery voltage, actually less on account of the decrements.

All of this has led to considerable speculation concerning the question: do currents extinguish precisely at a normal current zero?

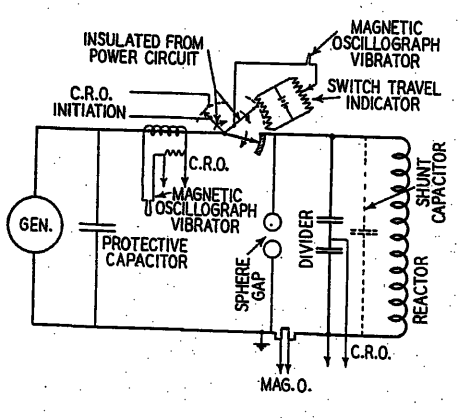

**Figure 1. Single-frequency test circuit**

## Current Interruption

A switch will endeavor to open the circuit at the instant when the contacts begin to part, but an arc forms and

(*B*)—High-frequency component due to stored electrostatic energy in the capacitance

(*C*)—High-frequency component due to stored magnetic energy in the reactance

maintains the circuit until it is disrupted by the surrounding dielectric. Ordinarily, this occurs so close to a normal current zero that it appears on the oscillograms as interruption at a current zero. In order to examine the exact instant of rupture in more detail, records were taken with the 3-element cathode-ray oscillograph developed by E. J. Wade.[3] A single cycle of normal frequency was drawn out so as to occupy the whole length of the film (24 inches) but of only half an inch amplitude; so that the point of rupture was very distinct. It was found that the contactor could abruptly interrupt the current at values of the order of 5 amperes, which in these tests corresponded to cut-off some 10 degrees from a normal current zero. Two examples are given in figure 2*a*. The ensuing high-frequency oscillations in the current waves through the reactor are clearly shown, and in figure 2*b* the corresponding high-frequency recovery voltages. The circuit consisted of a reactor of 0.25 henry inductance shunted by a capacitance of 0.003 microfarad. The natural frequency of the circuit was thus

$$f_n = \frac{1}{2\pi\sqrt{LC}} = \frac{1{,}000}{2\pi\sqrt{0.25 \times 0.003}} = 5{,}800 \text{ cycles per second}$$

or about 100 times normal frequency. In appendix I it is shown, on the assumption of abrupt current interruption that the recovery voltage is approximately:

$$e \cong E\left[\cos(\omega t - \theta) - (\cos\theta + \frac{a}{\omega}\sin\theta)\epsilon^{-at}\cos wt - \frac{w}{\omega}\sin\theta\epsilon^{-at}\sin wt\right]$$

in which $E\cos(\omega t-\theta)$ is the normal frequency voltage, $\theta$ the angle from a current zero at which interruption occurs, $(w/2\pi)$ the natural frequency, and $a$ the decrement factor. There are 2 components to the high-frequency oscillation. The cos $wt$ term is that present when interruption occurs at a normal current zero, $\theta = 0$, for then

$$e = E[\cos\omega t - \epsilon^{-at}\cos wt]$$
$$\cong E(1 - \cos wt)$$

for short times and no decrement. This is the recovery voltage of the prevailing theory[1] and is seen not to exceed twice normal peak voltage.

The sin $wt$ term exists only for finite values of $\theta$, but since $w/\omega$ is usually quite high (100:1 in figure 2) it is clear that even a very small value of $\theta$ will result in high voltages. It is this term which is responsible for the excessive voltages experienced during switching. It is:

$$E\frac{w}{\omega}\sin\theta = E\frac{\text{(natural frequency)}}{\text{(applied frequency)}} \times \frac{\text{(cut-off current)}}{\text{(normal crest current)}}$$
$$= \sqrt{\frac{L}{C}}\,\text{(cut-off current)}$$

This equation shows that:

(a). The higher the natural frequency the higher the voltage, hence the voltage increases inversely as the square root of the capacitance. (It will be shown later that this is not necessarily true if restriking occurs.)

(b). The voltage is directly proportional to the cut-off current. This cut-off current is probably a function of the switch speed, type of switch, and other factors.

Thus, if no restriking occurs, the recovery voltage consists essentially of 3 terms:

$$e = \underbrace{\left\{\begin{matrix}\text{normal}\\\text{frequency}\\\text{recovery}\\\text{voltage}\end{matrix}\right\}}_{I} + \underbrace{\left\{\begin{matrix}\text{high-frequency}\\\text{term depending}\\\text{upon the capaci-}\\\text{tor voltage at}\\\text{instant of cut-off}\end{matrix}\right\}}_{II} + \underbrace{\left\{\begin{matrix}\text{high-frequency}\\\text{term depending}\\\text{upon the reactor}\\\text{current at instant}\\\text{of cut-off}\end{matrix}\right\}}_{III}$$

of which the last is by far the most important. These components are shown as vectors in figure 3.

Since, however, the tendency is to rupture very close to a normal current zero, the probability of large cut-off currents, and correspondingly high voltages, is not great. The following results, obtained by E. A. Elge, from sphere gap measurements on a 0.25-henry reactor shunted by a 0.0003-microfarad capacitance, give the number of switch operations which were necessary to cause gap sparkover. It will be noted that the probability of voltages greater than 7 times normal is very much less than for the small voltages.

### Arc Voltage

The actual mechanism of current interruption by any switch must involve some sort of a rapidly increasing arc drop which breaks the circuit when the resulting transient switch current passes through zero. Mr. C. Concordia, in

**Table I**

| Gap Setting, Kv (Rms) | Times Normal Voltage | Switching Operations to Cause Gap Sparkover |
|---|---|---|
| 3.0 | 1.5 | 1 |
| 5.25 | 2.62 | 3 |
| 6.0 | 3.0 | 3 |
| 7.0 | 3.5 | 1 |

an unpublished report, has calculated the recovery voltage assuming the arc drop to increase linearly as a function of time, and under this assumption finds that for slow rates of increase of the arc drop the recovery voltage tends to become independent of the circuit constants, while for fast rates it tends to become independent of the switch characteristics. But the oscillograms of the present investigation show the rupture sufficiently abrupt with respect to the natural periods, so that for all practical purposes it is sufficient to regard the current interruption as instantaneous. The current cut-off is equivalent to the

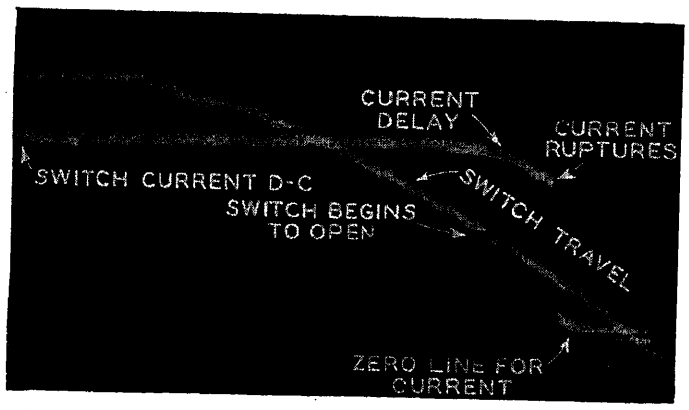

**Figure 4. Oscillogram of a d-c current interruption and switch travel**

application of a steep wave front. It is well known that a wave front even as long as 25 per cent of the natural period will succeed in developing at least 90 per cent of the oscillation that a rectangular wave front could develop (see, for example, figure 113 of reference 4). For circuits with much higher natural frequencies than those with which this investigation is concerned, it may be expedient to consider more carefully the arc characteristics. The abruptness of the cut-off is clearly shown on the oscillogram of figure 4 for the interruption of a d-c current.

## Restriking

When the switch arc extinguishes the first time, a high-frequency oscillation is initiated. This transient starts with the current in the reactor and the voltage across the capacitor at the instant of rupture as initial values, and if not interfered with, the transient develops as previously described. As the transient voltage increases, the switch contacts are opening, thus increasing the dielectric recovery strength of the switch. If the transient voltage overtakes the dielectric recovery, the arc will restrike, and the switch then makes a second attempt to open the circuit. At this second attempt the recovery voltage transient is very similar to that following the first attempt, except that the amplitude of the oscillation is reduced. In the meantime the switch has been continuously opening, acquiring greater dielectric strength, and therefore it will be a longer time before the arc again restrikes, if at all. Thus current interruption is a race between the rate of increase of dielectric strength and the rate of rise of the recovery voltage, and restriking gives the switch time to open.

The general equations of the restriking phenomena are given in appendix II. The principal term in the voltage transient following the $k$'th restrike is:

$$e \cong -wLI_k\epsilon^{-a(t-t_k)}\sin w(t-t_k)$$

in which $I_k$ is the initial current in the reactor at the start of the $k$'th restrike and lags the voltage by approximately 90 degrees, and $t_k$ is the instant at which this restrike occurs, counting time from the initial current rupture. The vector diagram of the successive restriking, taking cognizance of the above term only, is shown in figure 5*A*, the instantaneous values being the projections on the vertical axis. The sequence of events is as follows: at $t_0=0$ the switch ruptures the circuit for the first time and the voltage vector

$$e = -wLI_0\epsilon^{-at}\sin wt$$

begins to revolve at the high frequency angular velocity $w$, and to shrink exponentially. At time $t_1$ when the instantaneous voltage is $e_1$ the voltage is sufficient to break down the dielectric of the switch and the first restrike occurs. The current in the reactor at this instant is

$$I_1 = I_0\epsilon^{-at_1}\cos wt_1$$

and the new voltage transient is

$$e = -wLI_0\cos wt_1\epsilon^{-at}\sin w(t-t_1)$$

or the previous transient reduced by $\cos wt_1$ and starting at time $t_1$. By the same reasoning the voltage following the second restrike is

$$e = -wLI_0\cos wt_1\cos w(t_2-t_1)\epsilon^{-at}\sin w(t-t_2)$$

Successive restriking of this nature continues to take place until the dielectric strength of the switch has increased to a value such that the transient voltage is unable to break it down. Thereafter the transient voltage is simply a damped oscillation, shown in figure 5 as a logarithmic spiral.

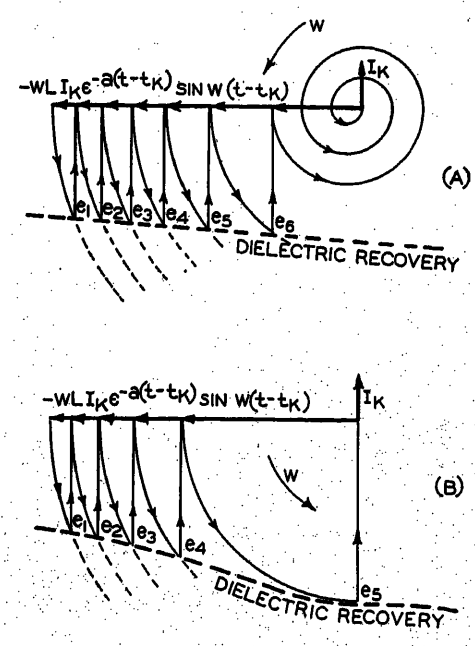

**Figure 5. Vector relationships in restriking phenomena**

(*A*)—Successive restriking with a final oscillation

(*B*)—Successive restriking without a final oscillation

If, now, the last restrike occurs at the crest of the oscillation, as shown in figure 5*B*, the current is zero, and there will be no damped oscillation associated with the electromagnetic energy, although an oscillation will exist due to the electrostatic energy which has been neglected in the foregoing.

### Effect of Dielectric Recovery Rate

In figure 6 the dielectric recovery is shown as a straight line starting at the same initial value, but with 4 different slopes, or rates. Only part of the first half cycle of each oscillation of voltage is shown. Actually, the transient is a damped oscillation about the time axis. In figure 6*a* the dielectric recovery (*d.r.*) is so fast that the oscillation reaches crest without restriking, and the recovery voltage (*r.v.*) is the maximum possible for a given angle of rupture $\theta$. If, now, the *d.r.* is slowed down, as in 6*B*, the rising *r.v.* meets the *d.r.* at point *a*, and then restrikes instead of rising on to the previous crest $V_1$, and the second attempt carries the crest to some value $V_2'$, less than $V_1$. In 6*c* the *d.r.* has been reduced so as to involve 2 restrikes, while in 6*D* it has been reduced to show 3 restrikes, and $V_4''' < V_3''' < V_2''' < V_1'''$.

### Effect of Initial Angle of Rupture

As previously discussed, for an unhindered oscillation the amplitude of the *r.v.* is directly proportional to the cut-off current, that is proportional to sin $\theta$ where $\theta$ is the angle from a current zero at which the switch makes its first attempt to open the circuit. But if restriking occurs this is not true. Figure 7 illustrates the effect of the cut-off angle $\theta$ when restriking occurs, the *d.r.* being the same for all angles. In 7*A* where $\theta = 4$ degrees, 3 restrikes occur in succession before the *d.r.* finally escapes the *r.v.* In 7*B* the angle is $\theta = 3$ degrees, and only one restrike occurs, and on this account $V_2'$ is very little less than $V_4$, although $V_1' = 0.75\ V_1$. In 7*C* at $\theta = 2$ degrees there is no restriking and $V_1'' = 0.5\ V_1$. A further reduction to $\theta = 1$ degree reduces the *r.v.* to $V_1''' = 0.25\ V_1$.

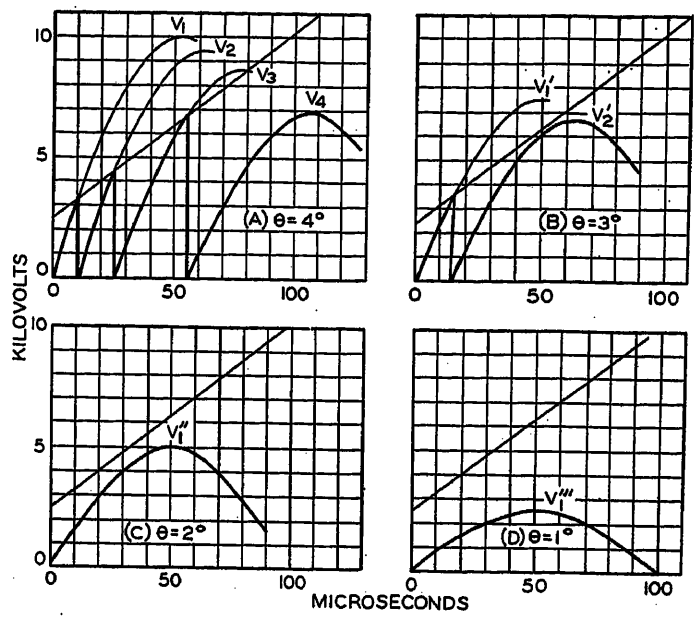

**Figure 7. Effect of initial angle of rupture**

Natural period—$T$ = 200 microseconds

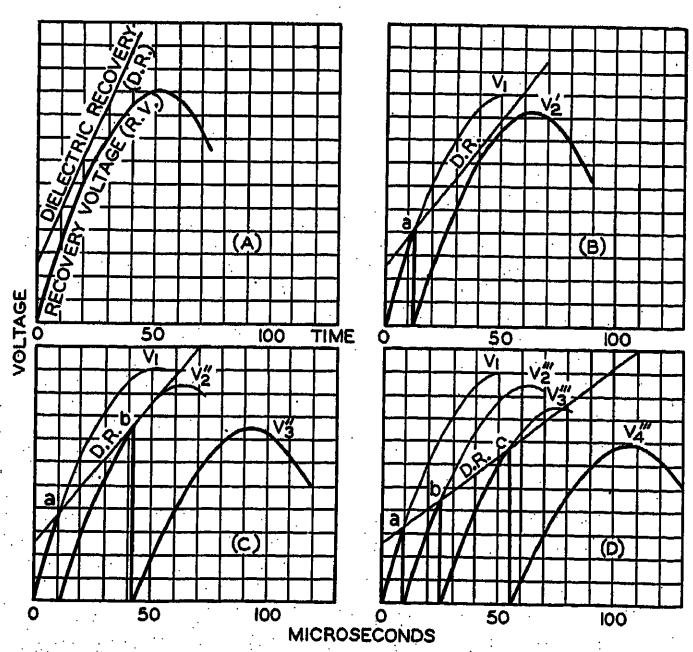

**Figure 6. Effect of dielectric recovery rate**

Initial angle of rupture—$\theta$ = 4 degrees
Natural period—$T$ = 200 microseconds

### Effect of Capacitance

When restriking occurs, it is quite possible to obtain higher *r.v.* by adding capacitance, which is quite contrary to the case when no restriking occurs. The addition of capacitance does 2 things: (1) it reduces the amplitudes proportional to $1/\sqrt{C}$; and (2) it increases the natural period proportional to $\sqrt{C}$. Therefore, as shown in figure 8, it may be that the number of restrikes can be reduced if the natural period is increased, and on this account a higher voltage produced than would result with more restrikes at a smaller capacitance. Thus in 8*A* 3 restrikes occur before the oscillation develops with a crest of $V_4 = 70$ per cent. Increasing the capacitance by 35 per cent as in 8*B* increases the natural period just enough to permit only one restrike, and the resulting crest voltage $V_2 = 76$ per cent; while in 8*C*, where the capacitance has been doubled, restriking is avoided entirely and the *r.v.* crest is $V_1 = 72$ per cent. A further increase in capacitance, as in 8*D*, can only result in a reduction of *r.v.* crest, in this case to $V_1 = 57$ per cent.

## Oscillographic Evidence

### Effect of Capacitance

The foregoing effects are well illustrated by the reactor voltage oscillograms of figure 9. In 9*A* the shunt capacitance was only 0.004 microfarad and the natural period 93 microseconds. A few restrikes are discernible at the beginning of the transient, near the crest of the normal frequency voltage. Normal voltage was 1,400 volts (crest), and the transient carried to 3.5 times normal.

For 9*B* the capacitance was 0.25 microfarad and the natural period 1,360 microseconds. This oscillogram exhibits a single restrike. The voltage is materially less than in 9*A* on account of the great increase in capacitance.

For 9*C* the capacitance was 0.5 microfarad and the natural period 960 microseconds. The transient was too slow and of too low amplitude to permit restriking.

### Dielectric Recovery

In figures 6, 7, and 8 the dielectric recovery was shown as a straight line starting at a finite value. Actually, this recovery must start at zero, and apparently at first increases very rapidly and then at a more uniform rate. But it must not be supposed that the *d.r.* is always at a uniform rate. The envelope of the restrike is, in fact, the curve of dielectric recovery against time; for such a curve gives the breakdown voltages at various instants. When matched with a record of the switch travel against time it is possible to correlate the *d.r.* with the switch opening. Records of this nature were taken as shown in the magnetic oscillogram of figure 4.

The erratic nature of some of the dielectric recoveries is illustrated by the oscillograms of figure 10. Thus in 10*A* 3 small restrikes are followed by a larger restrike, then another small one, and then a very pronounced final restrike, after which the switch succeeds in opening, and the circuit enters into its oscillation. In 10*B* the restriking repeats many times at essentially the same voltage before the switch suddenly becomes deionized and recovers. In 10*C* the restriking sequence starts to build up, but suffers a bad relapse lasting over many small restrikes before the circuit opens. In 10*D* a single restrike is followed by a half cycle of high-frequency oscillation, and then restriking occurs twice at the opposite polarity.

The envelope of restrikes has been plotted for most of the 74 oscillograms taken, and representative curves shown in figure 11. It is seen that the dielectric recovery is very erratic for this type of switch.

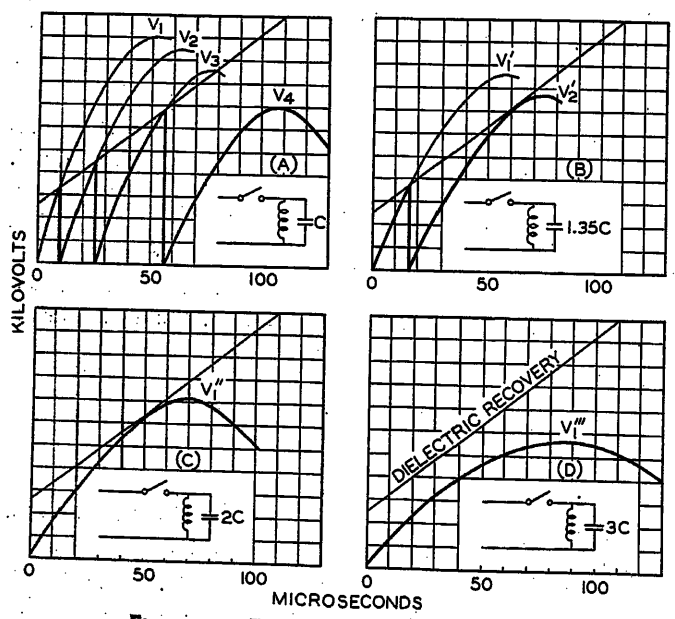

**Figure 8. Effect of shunt capacitance**

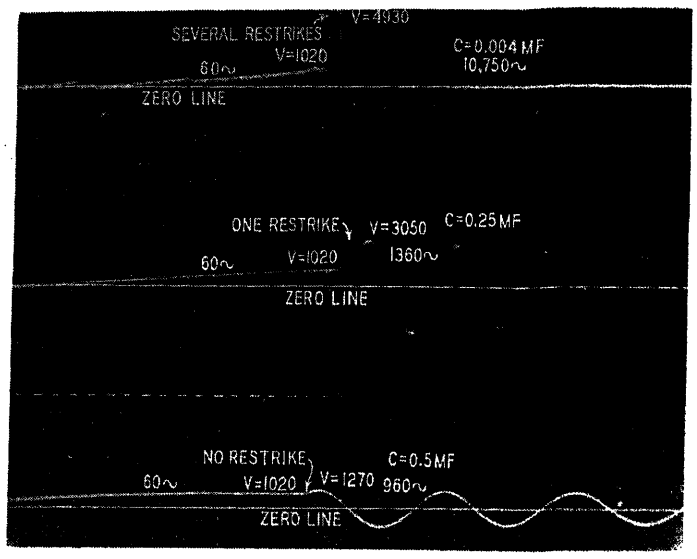

**Figure 9. Effect of capacitance**

Top—C = 0.004 microfarad, several restrikes
Middle—C = 0.25 microfarad, one restrike
Bottom—C = 0.5 microfarad, no restrikes

### Vanishing of the Oscillations

The higher up on the oscillation at which restrike occurs, other things being the same, the smaller the amplitude of the subsequent oscillation, and restrike on the crest practically discontinues the transient. The appropriate equations are given in appendix II, and the physical reason, as previously discussed, is simply that restrike at the crest of the voltage oscillation corresponds to zero current in the reactor, while immediately following restrike the voltage to which the capacitance is charged is the normal frequency voltage, so that the only energy supporting the subsequent oscillation is that of the capacitance charged to normal voltage.

This effect is illustrated in figure 12. These oscillograms are for a 125-volt d-c circuit, and as seen, the transient voltage at about 22 degrees results in a voltage of 8,400 volts (67 times normal). In 12*B* the restrike occurs at about 78 degrees and this is so close to a voltage peak that the subsequent oscillation is greatly reduced. In 12*C* and 12*D* the restrike occurs on the crest of the oscillation at about 90 degrees and the subsequent oscillation is barely discernible on the oscillograms. This small oscillation is really of normal voltage amplitude, but appears insignificant compared with the high transient voltage peaks.

### Shunt Resistors

The provision of a shunt resistor offers a parallel path for the reactor current after the switch has opened, and thereby limits the recovery voltage. There is a critical value of resistance $r = 0.5\sqrt{L/C}$ which suppresses the oscillations. In figure 13*B* is shown the effect of shunting a circuit of $L = 0.055$ and $C = 0.001$ with a resistance of

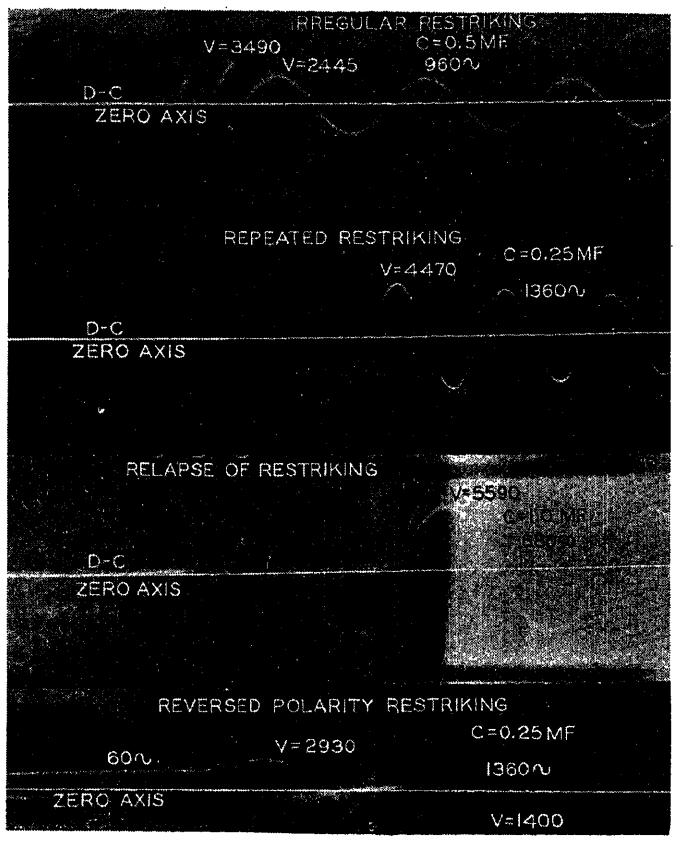

**Figure 10. Erratic nature of restriking**

5,000 ohms. The critical resistance in this case is $r$ = 3,700 ohms, so that there is still a tendency to oscillate with 5,000 ohms.

Figure 13*C* shows the effect of a Thyrite shunt. Since this material has a resistance characteristic which is low for high voltages and high for low voltages, it is to be expected that when used as a shunt resistor the higher voltages will be prohibited, but free oscillation can develop at reduced voltage. The oscillogram of 13*B* confirms this.

The result of a step-by-step calculation, according to appendix II, is shown in figure 14. This shows that with an appropriate Thyrite shunt there is no excessive voltage across the switch contact, and the transient is a smooth curve free of oscillations. The Thyrite shunt not only limits the recovery voltage, but also substantially reduces the rate-of-rise, thereby lessening the duty on the breaker.

## Tests

The special testing technique for this investigation was worked out and supervised by E. J. Wade, and it was only through the use of his 3-element cathode-ray oscillograph[3] that suitable data were obtained. Preliminary tests were conducted by E. A. Elge, of which figure 2 is a sample. A total of some 250 oscillograms, both magnetic and cathode ray, were secured; and these cover 2 different reactors, 6 different shunt capacitances, constant and Thyrite shunt resistors, 2 different load ratio control switches, and both a-c and d-c switching.

A photograph of the standard *LR*-17 switch used in these tests is shown in figure 15. This switch is comparatively "fast," having a total switching time of 0.007 second, and an initial rate of opening of 0.004 millimeter per microsecond. For comparison, a *LR*-28 switch having a switching time of 0.020 second, and an initial rate of opening of 0.0015 millimeter per microsecond was also tried.

The test circuit is shown in figure 1, the essential elements being in heavy lines and the recording and auxiliary elements in light lines. The inductance for most of the tests was an oil-filled commercial reactor rated *OT*-60-369-1590-77.4, for load-ratio control, and had an inductance of 0.0055 henry. The capacitance varied from the 0.002 microfarad of the cathode ray oscillograph divider to shunts of 1.0 microfarad. The power supplies consisted of a 1,000-volt 20-ampere a-c source, and a 125-volt 25-ampere d-c source. To protect these sources from excessive switching surge voltages, and also to simulate an "infinite bus," a large protective capacitor of 0.5 microfarad was across the power supply but on the line side of the switch. The transient voltage across the reactor was recorded by one of the tubes of the 3-element cathode-ray oscillograph, through the capacitance divider.

A current transformer with a resistor across its secondary was intended to yield both cathode ray and magnetic oscillograms of the switch current. But these proved disappointing, as the flux trapped in the core of the current transformer, upon interruption of the current through the switch, decayed exponentially through the resistor and gave an entirely erroneous picture of the current cut-off. This was confirmed by changing the value of the resistor,

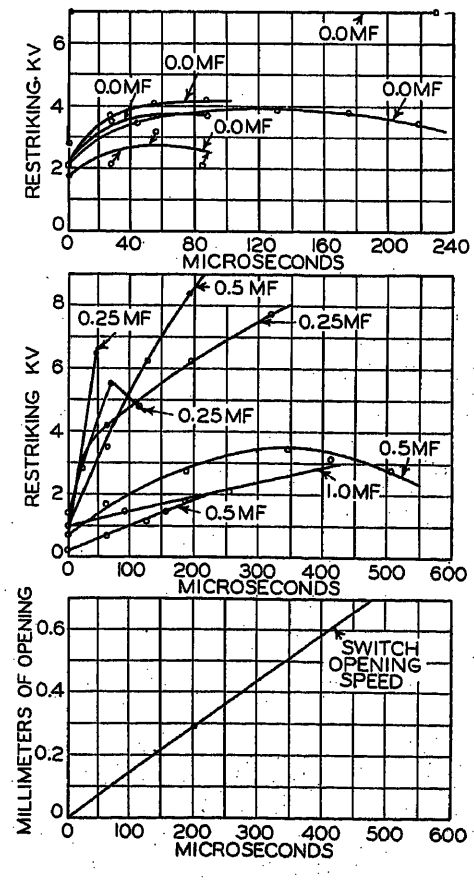

**Figure 11. Dielectric recovery**

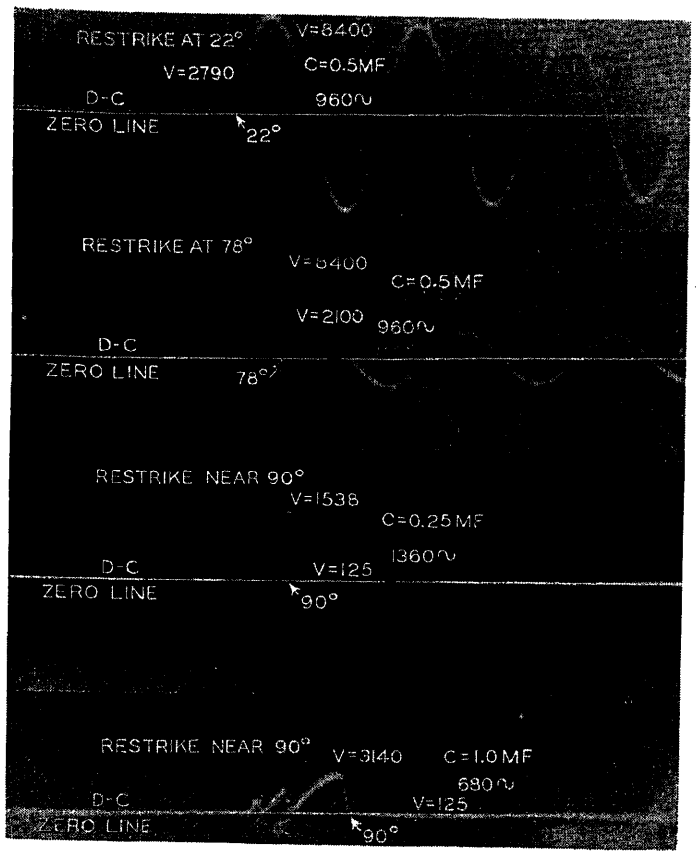

**Figure 12. Effect of the point on the high-frequency oscillation at which restrike occurs (d-c switching)**

which changed the time constant of the exponential decay. In addition, this current transformer broke down sometime during the tests and was defective for an unknown period. Magnetic oscillograms of the circuit were also obtained from a series resistor. These, however, did not show the point of current cut-off sufficiently distinctly to be of much use.

A sphere gap gave verification of the order of magnitude of the overvoltages. Since the voltage for a given circuit depends upon the intial angle of current rupture and on the number of restrikes, it was necessary to make successively more switching operations for each higher gap setting in order to be sure that the highest possible voltages were obtained.

The switch travel indicator for recording the rate of opening of the switch contacts was merely an auxiliary arm attached to the switch and arranged to move over an excited resistor as shown in figure 1. The vibrator of the magnetic oscillograph was connected between the switch auxiliary arm and a point on a potentiometer which was adjusted so as to give zero vibrator deflection just as the switch contacts began to part. A typical record is shown in figure 4. The total switch travel from the instant when its motion is initiated until it is completed is roughly a half cycle of a cosine curve (cos $at$), but over the range from the instant when the contacts begin to open until the current is finally interrupted, the switch travel is essentially at constant speed.

The control circuit of figure 16 was devised, so that the pressing of a button started in proper sequence the driving motors of the switch and of the magnetic oscillograph. A second auxiliary arm on the switch was arranged to initiate the cathode-ray oscillograph by making a contact prior to the opening of the switch.

All of the oscillograms were analyzed by W. D. Whinery, Jr., and the magnitudes, frequencies, number of restrikes, restriking peaks, and other pertinent information tabulated. The examples given in the paper are typical and were selected with a view to illustrating the various characteristics of the phenomena.

## Conclusions

This study has shown that, for the types of circuit and switches employed, switching surges may be characterized as follows:

1. The dielectric recovery strength of the switch was very erratic, and no correlation has been found with the factors involved. A 3-to-1 increase in switch speed did not make any material difference in the recovery rate.

2. The current interruption by the switch usually occurred at or very close to a normal-frequency current zero, but rupture at other than current zero was by no means uncommon. Apparently the current cut-off was sufficiently abrupt so that for all practical purposes it may be regarded as instantaneous. The highest a-c cut-off current observed was about 5 amperes at 10 degrees from a current zero. This, incidentally, is the order of current snapping which sometimes occurs in mercury-arc rectifiers. D-c currents were abruptly interrupted at about 20 amperes.

3. If no restriking occurs, the recovery voltage consists essentially of 3 terms:

$$e = \left\{\begin{matrix}\text{normal}\\ \text{frequency}\\ \text{recovery}\\ \text{voltage}\end{matrix}\right\} + \left\{\begin{matrix}\text{high frequency}\\ \text{term depending}\\ \text{on the voltage at}\\ \text{instant of current}\\ \text{current cut-off}\end{matrix}\right\} + \left\{\begin{matrix}\text{high frequency}\\ \text{term depending}\\ \text{on magnitude of}\\ \text{of the cut-off}\\ \text{current}\end{matrix}\right\}$$

The first term is, of course, normal voltage. The second term is a maximum for current interruption at a normal current zero, for the voltage to which the capacitance is charged is then a maximum. But this term never exceeds normal voltage. It is the third term

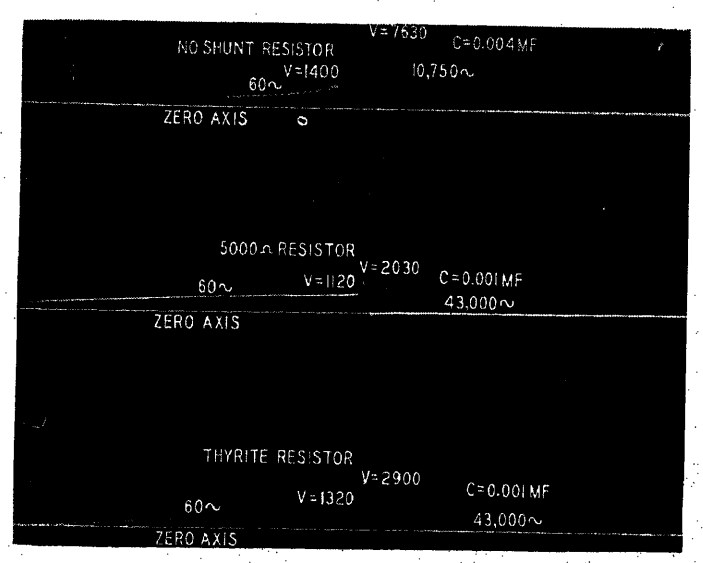

**Figure 13. Effect of shunt resistor**

which is responsible for the really high voltages. It represents the stored magnetic energy in the reactance, and is therefore greater the greater the current in the reactor at the instant of cut-off. Thus the further away from a current zero that rupture occurs, the higher the recovery voltage. The 2 high-frequency terms are in time quadrature and therefore do not add directly. Overvoltages of 18 times normal were obtained with a-c switching and 72 times normal with d-c switching.

4. Successive restriking was found to be the most influential factor of the recovery characteristic. Restriking was so abrupt as to be practically instantaneous and was followed by an immediate dielectric recovery.

5. The amplitude of the oscillation following the final restrike depends upon the point on the preceding oscillation at which restrike occurs, and if this happens near the crest, the transient can be reduced to normal voltage amplitude. A succession of restrikes reaching ultimate values many times normal, and then suddenly terminating in a very trivial oscillation, present a rather uncanny appearance on the oscillograms, but are simply explained and easy to calculate.

6. The addition of shunt capacitance will always decrease the recovery voltage crests if there is no restriking, but if restriking occurs it is possible to get higher voltages by adding capacitance; because the capacitance decreases the frequency to the same extent that it decreases the amplitude, and this may allow the switch to finally open with fewer restrikes.

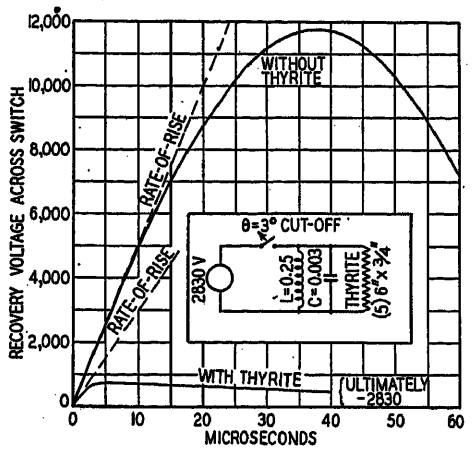

**Figure 14. Effect of Thyrite shunt on recovery voltage (calculated)**

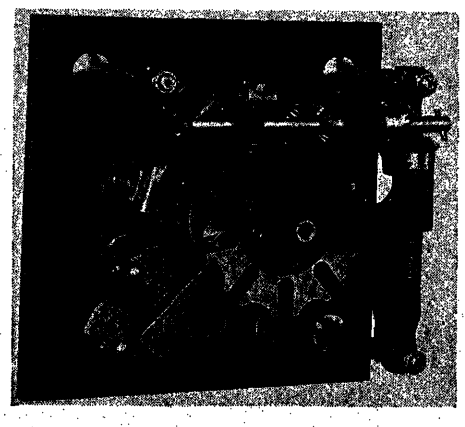

**Figure 15. Load-ratio control switch used in tests**

7. A shunt resistor can be chosen which will suppress the transient recovery voltage to any desired extent. This resistor may be either constant or of such a material as Thyrite. A Thyrite resistor not only suppresses the overvoltage, but also reduces the rate of rise.

# Appendix I

## Finite Current Cut-Off

This appendix describes the modification necessary in the conventional theory to account for the great amplitude of the high frequency oscillation in the recovery voltage. Referring to figure 17 there is shown a generator supplying current to a reactor $L$ having series resistance $R$, and shunted by a capacitance $C$ and a leakage

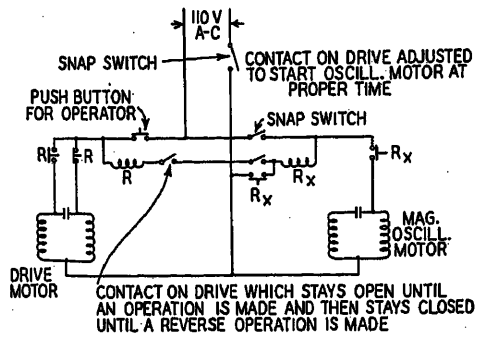

**Figure 16. Control circuit**

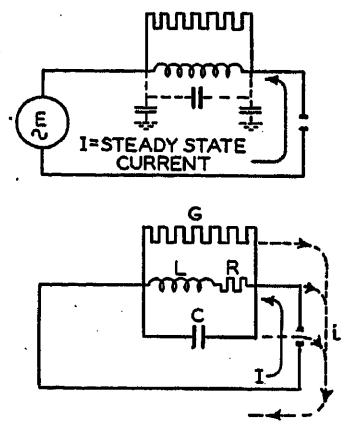

**Figure 17. The elementary circuit**

(A)—Actual circuit

(B)—Equivalent electric circuit

conductance $G$. The series resistance $R$, under high frequency conditions, will be many times the steady state d-c resistance of the winding. The capacitance $C$ is the effective circuit capacitance including the series and shunt capacitance of the reactor winding, leads, etc. It is of the order of 0.001 microfarad, unless extra capacitance in the form of an actual capacitor is deliberately added. It may be remarked here, that the smaller the inherent capacitance of the circuit, the more important it is; because the amplitude of the high-frequency recovery voltage is almost inversely proportional to the square root of the circuit capacitance. The leakage conductance $G$ is rather indefinite, unless a shunt resistor is connected across the reactor terminals. It will be shown that the high-frequency oscillation can be wiped out by a resistor of a few thousand ohms.

The conventional mathematical device for calculating recovery voltages (across the breaker terminals) as introduced by R. H. Park and W. F. Skeats,[1] consists in superposing an equal but opposite current through the breaker contacts at the instant of rupture. Thereafter, this superposed current cancels the steady state current through the breaker, and since there was no voltage across the breaker (the contacts being closed) associated with the steady state current, the "recovery voltage" must be due entirely to the superposed current. If, now, we assume the current to rupture at an angle $\theta$ prior to a current zero, the superposed current is, in operational form:

$$i = I \sin(\omega t - \theta) = I \frac{p\omega \cos\theta - p^2 \sin\theta}{p^2 + \omega^2} \qquad (1)$$

The operational impedance of the circuit, as viewed from the breaker contacts, is

$$Z(p) = \frac{R + pL}{LCp^2 + (LG + RC)p + (RG + 1)} \tag{2}$$

The operational equation for the recovery voltage then is

$$e = Z(p) \cdot i = \frac{I}{C} \frac{p(p + b)(\omega \cos \theta - p \sin \theta)}{(p^2 + \omega^2)(p^2 + 2ap + A^2)} \tag{3}$$

in which

$$a = \frac{1}{2}\left(\frac{G}{C} + \frac{R}{L}\right) \qquad b = \frac{R}{L} \qquad A^2 = \frac{RG + 1}{LC} \tag{4}$$

The solution of 3 is easily effected by the expansion theorem, and is

$$e = \frac{\omega I}{Cw^2}\left\{\sqrt{\frac{(1 + b^2/\omega^2)}{(1 + a^2/w^2 - \omega^2/w^2)^2 + 4a^2\omega^2/w^4}} \times \sin(\omega t - \theta + \phi_1 - \phi_2) + \sqrt{\frac{\left[1 + \left(\frac{b - a}{w}\right)^2\right]\left[\left(\cos\theta + \frac{a}{\omega}\sin\theta\right)^2 + \left(\frac{w}{\omega}\sin\theta\right)^2\right]}{(1 - a^2/w^2 - \omega^2/w^2)^2 + 4a^2/w^2}} \times \epsilon^{-at} \sin(wt + \phi_3 - \phi_4 + \phi_5)\right\} \tag{5}$$

where

$$w^2 = A^2 - a^2$$

$$\phi_1 = \tan^{-1}(\omega/b)$$

$$\phi_2 = \tan^{-1}\left(\frac{2a\omega}{a^2 - \omega^2 + w^2}\right)$$

$$\phi_3 = \tan^{-1}\left(\frac{w}{b - a}\right)$$

$$\phi_4 = \tan^{-1}\left(\frac{w \sin\theta}{\omega\cos\theta + a\sin\theta}\right)$$

$$\phi_5 = \tan^{-1}\left(\frac{2aw}{a^2 + \omega^2 - w^2}\right)$$

If, as would normally be the case, $w$ is large compared with $a$, $b$, and $\omega$, and $\omega$ is large compared to $b$, there is approximately $\phi_1 \cong 90$ degrees, $\phi_2 \cong 0$ degrees, $\phi_3 \cong 90$ degrees, $\phi_5 \cong 180$ degrees, $w^2 \cong 1/LC$ and 5 becomes

$$e \cong E\left\{\cos(\omega t - \theta) - \sqrt{(\cos\theta + \frac{a}{\omega}\sin\theta)^2 + \left(\frac{w}{\omega}\sin\theta\right)^2} \times \epsilon^{-at}\cos(wt - \phi_4)\right\} \tag{6}$$

where $E = \sqrt{R^2 + \omega^2 L^2}\, I$ = normal voltage

### Rupture at "Current Zero"

Putting $\theta = 0$, then $\phi_4 = 0$ and 6 yields

$$e = E(\cos\omega t - \epsilon^{-at}\cos wt) \tag{7}$$

and it is usually assumed that the decrement is negligible. Then there is the usual formula

$$e = E(\cos\omega t - \cos wt) \cong E(1 - \cos wt) \text{ for short times} \tag{8}$$

According to this, the recovery voltage consists of a simple oscillation about normal voltage as an axis, and the amplitude of the oscillation is the same as normal voltage.

### Rupture at Finite Current

Unless a shunt resistor has been added, $G$ will be so small that the approximation 6 holds, and it may be expanded into the form

$$e = E\left\{\cos(\omega t - \theta) - (\cos\theta + \frac{a}{\omega}\sin\theta)\,\epsilon^{-at}\cos wt - \left(\frac{w}{\omega}\sin\theta\right)\epsilon^{-at}\sin wt\right\} \tag{9}$$

and the last term is responsible for the very high voltages experienced. It is

$$E\frac{w}{\omega}\sin\theta = E\left(\frac{\text{natural frequency}}{\text{applied frequency}}\right)\left(\frac{\text{cut-off current}}{\text{normal crest current}}\right) = \sqrt{\frac{L}{C}}\, I_{c.o.} \tag{10}$$

This equation shows that:
($a$). The higher the natural frequency of the circuit the greater the amplitude. Since the natural frequency is very closely

$$w = \sqrt{A^2 - a^2} \cong \frac{1}{\sqrt{LC}} \tag{11}$$

it is clear that the amplitude of oscillation is inversely proportional to the square root of the capacitance. Hence, the addition of capacitance will decrease the amplitude.
($b$). The higher the current at which rupture occurs the greater the voltage. In fact, the recovery voltage is directly proportional to the cut-off current. It is not yet clear if there is a maximum cut-off current at which a given switch can rupture the circuit. If so, then the higher the normal crest current in a circuit. the smaller the recovery voltage, since it is the *ratio* of *cut-off* to *normal* current which is important in equation 11; and therefore if there is an upper limit to the cut-off current (for a given switch), normal current is important.

As an example let:

$E = \sqrt{2} \times 2{,}000 = 2{,}828$
$L = 0.25$ henrys
$C = 0.003$ microfarad
$\omega = 2\pi f = 377$
$a = 0.003 \times 10^6$
$b = 0$
$\theta = 10°$ ($\sin\theta = 0.173$)

$$w = \frac{1}{\sqrt{LC}} = 36{,}500$$

By 9, if $t$ is in microseconds

$$e = 2828\,[\cos(0.000377t - 10°) - (0.985 + \frac{3000}{377} \times 0.173) \times \epsilon^{-0.003t}\cos 0.0365t - \frac{36500}{377} \times 0.173\,\epsilon^{-0.003t}\sin 0.0365t]$$
$$= 2828\cos(0.000377t - 10°) - 6690\,\epsilon^{-0.003t}\cos 0.0365t - 47400\,\epsilon^{-0.003t}\sin 0.0365t$$

This has a maximum of 43,000 volts, or 15 times normal. The value of $a$ used in this problem corresponds to a leakage resistance of about 55,000 ohms.

### Shunt Resistor

The circuit can be rendered nonoscillatory by the addition of a shunt resistor such that

$$(a^2 \geq A^2) \text{ or } \frac{1}{4}\left(\frac{G}{C} + \frac{R}{L}\right)^2 \geq \left(\frac{RG + 1}{LC}\right) \tag{12}$$

or approximately

$$G \geq 2\sqrt{\frac{C}{L}} \tag{13}$$

Under this condition the high frequency oscillation is adequately suppressed. Taking the example in the previous case, and assuming a shunt resistor of 6,000 ohms, we have by 4

## Table II

| Event | Instant | Initial Conditions: Current | Initial Conditions: Voltage | Dielectric Strength | Switch: Voltage | Switch: Current | Reactor: Voltage | Reactor: Current |
|---|---|---|---|---|---|---|---|---|
| Begin to rupture $i_s(t_1, 0) = 0$ | 0 | $I_0 = -I \sin \theta$ | $E_0 = E \cos \theta$ | $f(t)$ | $i_s(t, 0)$ | $e(t, 0)$ | $i(t, 0)$ | |
| First rupture $E_s(t_1) = \bar{e}_s(t_1, t_1)$ | $t_1$ | $I_1 = i(t_1, 0)$ | $E_1 = e(t_1, 0)$ | $E_s(t)$ | $\bar{e}_s(t, t_1)$ | 0 | $\bar{e}(t, t_1)$ | $\bar{i}(t, t_1)$ |
| First restrike $i_s(t_2, t_2) = 0$ | $t_2$ | $I_2 = \bar{i}(t_2, t_1)$ | $E_2 = \bar{e}(t_2, t_1)$ | $f(t)$ | $i_s(t, t_2)$ | $e(t, t_2)$ | $i(t, t_2)$ | |
| Second rupture | $t_2$ | $I_3 = i(t_2, t_2)$ | $E_3 = e(t_2, t_2)$ | $E_s(t)$ | $\bar{e}_s(t, t_2)$ | 0 | $\bar{e}(t, t_2)$ | $\bar{i}(t, t_2)$ |

## Table III

| Event | Instant | Initial Conditions: Current | Initial Conditions: Voltage | Dielectric Strength | Switch: Voltage | Reactor: Voltage | Reactor: Current |
|---|---|---|---|---|---|---|---|
| First rupture $E_s(t_1) = \bar{e}_s(t_1, 0)$ | 0 | $I_0 = -I \sin \theta$ | $E_0 = E \cos \theta$ | $E_s(t)$ | $\bar{e}_s(t, 0)$ | $\bar{e}(t, 0)$ | $\bar{i}(t, 0)$ |
| First restrike $E_s(t_2) = \bar{e}_s(t_2, t_1)$ | $t_1$ | $I_1 = \bar{i}(t_1, 0)$ | $E_1 = E \cos(\omega t_1 - \theta)$ | $E_s(t)$ | $\bar{e}_s(t, t_1)$ | $\bar{e}(t, t_1)$ | $\bar{i}(t, t_1)$ |
| Second restrike $E_s(t_2) = e_s(t_2, t_2)$ | $t_2$ | $I_2 = \bar{i}(t_2, t_1)$ | $E_2 = E \cos(\omega t_2 - \theta)$ | $E_s(t)$ | $\bar{e}_s(t, t_2)$ | $\bar{e}(t, t_2)$ | $\bar{i}(t, t_2)$ |
| Third restrike | $t_2$ | $I_3 = \bar{i}(t_2, t_2)$ | $E_3 = E \cos(\omega t_2 - \theta)$ | $E_s(t)$ | $\bar{e}_s(t, t_2)$ | $\bar{e}(t, t_2)$ | $\bar{i}(t, t_2)$ |

$$a = \frac{1}{2}\left(\frac{167}{0.003}\right) = 28{,}000$$

$$w = \sqrt{A^2 - a^2} \cong \sqrt{\frac{1}{LC} - a^2} = \sqrt{\frac{10^6}{0.25 \times 0.003} - 28{,}000^2} = 23{,}450$$

Hence by 5 there is approximately

$$e = 2828\left(\frac{36500}{23450}\right)^2\left\{\frac{1}{2.42}\cos(0.000377t - 10°) + 11.28\,\epsilon^{-0.028t}\sin(0.02345t - 58.6°)\right\}$$

$$= 2828\cos(0.000377t - 10°) + 77500\,\epsilon^{-0.028t}\sin(0.02345t - 58.6°)$$

The high-frequency oscillation has a maximum at ($t = 73$) of 6,350 volts, and the total voltage does not exceed 3 times normal, as compared with 15 times normal for the case without shunt resistor.

Had the shunt resistor been "critical," as called for by 13—about 4,500 ohms—the transient term would have been of no concern. It is suggested that 13 be adopted as the proper criterion for a shunt resistor.

### Thyrite Shunt

When a Thyrite shunt resistor is employed to suppress the magnitude and rate-of-recovery of the transient, it is necessary to resort to step-by-step calculations. Assuming, as before, that the switch opens at an angle $\theta$ from a normal current zero, and neglecting the arc drop, the initial conditions immediately following rupture of the switch current are:

$$i_L = -I \sin \theta \tag{14}$$

$$e_c = E \cos \theta \tag{15}$$

$$i_s = 0 = i_L + i_R + i_C \tag{16}$$

Substituting increments for differentials there is

$$\Delta e_c = \frac{i_C}{C}\Delta t = -\left(\frac{i_L + i_R}{C}\right)\Delta t \tag{17}$$

$$e_c = E \cos \theta + \Sigma \Delta \theta_c \tag{18}$$

$$\Delta i_L = \frac{e_{av}}{L}\Delta t \tag{19}$$

$$i_L = -I \sin \theta + \Sigma \Delta i_L \tag{20}$$

$$i_R = \phi(e_c) = \text{Thyrite current as function of the voltage} \tag{21}$$

Herefrom the step-by-step calculation can be performed in the following sequence:

| $\Delta t$ | $t$ | $\Delta i_L$ | $i_L$ | $i_R$ | $\Delta e_c$ | $e_c$ |
|---|---|---|---|---|---|---|
| | 0 | | $-I \sin \theta$ | $\phi(E \cos \theta)$ | | $E \cos \theta$ |
| (1) | | (3) | | (5) | | |
| (2) | | (4) | | (7) | | (6) |

## Appendix II

### Recurrent Restriking

Current interruption at other than a normal current zero results in the initiation of a greatly magnified voltage transient. If this voltage transient is able to overtake the increasing dielectric strength of the opening switch contacts, the arc will restrike and thus postpone the final rupture of the circuit. A number of restrikes may occur in succession before the switch gap is able to sustain the recovery voltage. In effect, a series of restrikes is equivalent to circuit interruption at a lower current than prevailed at the first attempt; so that the transient recovery voltage is substantially reduced. Moreover, since the switch contacts have been continually parting during the restriking period, the dielectric strength of the opening switch has ample time to become established and effect the final rupture.

An additional interesting fact associated with restriking of the switch is the possibility of obtaining *higher* recovery voltages by increasing the circuit capacitance, which is quite contrary to the case when no restriking occurs. The reason for this is that the addition of capacitance not only reduces the crest of the transient recovery voltage (inversely as the square root of the capacitance), but also reduces the natural frequency in the same proportion. It is thus possible for the switch to open with fewer restrikes, or even to escape restriking entirely, if the natural frequency is reduced, and on this account a higher recovery voltage results. Of course, if capacitance is added beyond that necessary to just avoid restriking, there is a decrease of recovery voltage.

There are 2 kinds of "events" associated with recurrent restriking of the switch arc: (*a*) the characteristic transient during arcing and, (*b*) the characteristic transient when the switch is clear. Each of these transients depends upon the currents and voltages existing at the initiation of the event; and these initial values are determined from the corresponding end conditions of the preceding event.

The analysis consists, then, in deriving the appropriate equations for each kind of transient, and the formulation of a procedure for determining the integration constants in proper sequence. In the interests of simplicity a circuit consisting of $L$ and $C$ in parallel will be considered.

### Arcing Conditions

During arcing of the switch the voltage applied to the circuit is

$$e = E \cos(\omega t - \theta) - f(t) \tag{1}$$

in which $E \cos(\omega t - \theta)$ is the applied normal frequency voltage and $f(t)$ is the arc drop expressed as a function of time $t$. More generally, the arc drop depends upon the current, kind of contacts, and other factors, but will be here regarded merely as a function of the switch opening, hence of time. Park and Skeats[1] have given an example (their figure 12) in which the arc drop at the instant of clearing was taken into account in calculating the recovery transient. Recently C. Concordia, in an unpublished report, has calculated the recovery voltage assuming the arc drop to be a linear function of time $Kt$, and under this assumption has found for slow rates of increase of the arc voltage that the recovery voltage tends to become independent of the circuit constants, while for fast rates it tends to become independent of the switch characteristics.

Adhering, for the sake of generality, to $f(t)$ as the arc drop, the current through the inductance is

$$i = \frac{1}{L}\int [E \cos(\omega t - \theta) - f(t)]\, dt = A + \frac{E}{\omega L}\sin(\omega t - \theta) - F(t) \tag{2}$$

in which $A$ is an integration constant and

$$F(t) = \frac{1}{L}\int f(t) \cdot dt \tag{3}$$

If $i = I_j$ at $t = t_j$ then

$$i = I_j + \frac{E}{\omega L}[\sin(\omega t - \theta) - \sin(\omega t_j - \theta)] - [F(t) - F(t_j)] \tag{4}$$

The capacitance current is

$$i_c = C\frac{de}{dt} = -\omega CE \sin(\omega t - \theta) - C \cdot f'(t) \tag{5}$$

and the total switch current is the sum of (4) and (5) or

$$i_s = I_j + \frac{E}{\omega L}[(1 - \omega^2 LC)\sin(\omega t - \theta) - \sin(\omega t_j - \theta)] - [F(t) - F(t_j)] - C \cdot f'(t) \tag{6}$$

If $f(t)$ is known, or assumed, the transcendental equation 6 determines the instant $t_{j+1}$ at which the switch current is passed through zero; and then (1) and (4) give the capacitor voltage and inductance current at this instant.

### Nonarcing Condition

When there is no arc across the switch the differential equation is

$$\frac{d^2 i}{dt^2} + \frac{i}{LC} = 0 \tag{7}$$

for which the solution is

$$i = A \cos wt + B \sin wt \tag{8}$$

and

$$e = L\frac{di}{dt} = -wLA \sin wt + wLB \cos wt \tag{9}$$

in which

$$w = \frac{1}{\sqrt{LC}}$$

If $i = I_k$ and $e = E_k$ at $t = t_k$ these give

$$\bar{i} = I_k \cos w(t - t_k) + \frac{E_k}{wL}\sin w(t - t_k) \tag{10}$$

$$\bar{e} = -wLI_k \sin w(t - t_k) + E_k \cos w(t - t_k) \tag{11}$$

in which bars have been placed over the quantities to distinguish them from the corresponding quantities under the arcing condition. The voltage across the switch is

$$\bar{e}_s = E \cos(\omega t - \theta) - \bar{e} \tag{12}$$

and the dielectric strength of the open switch will be taken as a function of time $E_s(t)$. Here again, the dielectric recovery strength is probably a function of the previous arc current and other factors, but will be considered as a simple function of the switch opening, that is of the time. It is clear from the test results that $E_s(t)$ is not linear. In many cases it first decreases and then increases, and is sometimes very erratic.

### Restriking

Suppose the switch makes its first attempt to open the circuit at time $t_j = t_0 = 0$ at which instant

$$e(0) = E_0 = E \cos\theta + f(0) \tag{13}$$

$$i(0) = I_0 = \frac{-E}{\omega L}\sin\theta \tag{14}$$

Hence by (6) the switch current is

$$i_s(t, 0) = \frac{E}{\omega L}(1 - \omega^2 LC)\sin(\omega t - \theta) - F(t) + F(0) - C \cdot f'(t) \tag{15}$$

Equating (15) to zero and solving for $t = t_k = t_1$ gives the instant at which the current extinguishes, at which instant

$$\text{by (1)} : e(t_1, 0) = E \cos(\omega t_1 - \theta) + f(t_1) = E_1 \tag{16}$$

$$\text{by (4)} : i(t_1, 0) = \frac{E}{\omega L}\sin(\omega t_1 - \theta) - F(t_1) + F(0) = I_1 \tag{17}$$

Substituting (16) and (17) into (10) and (11) there is

$$\bar{i}(t, t_1) = I_1 \cos w(t - t_1) + \frac{E_1}{wL}\sin w(t - t_1) \tag{18}$$

$$\bar{e}(t, t_1) = -wLI_1 \sin w(t - t_1) + E_1 \cos w(t - t_1) \tag{19}$$

$$\bar{e}_s(t, t_1) = E \cos(\omega t - \theta) + wLI_1 \sin w(t - t_1) - E_1 \cos w(t - t_1) \tag{20}$$

This condition persists until a time $t = t_j = t_2$ such that

$$\bar{e}_s(t_2, t_1) = E_s(t_2) \tag{21}$$

when the arc restrikes. The end conditions at $t = t_2$ are then given by (18) and (19) as

$$\bar{i}(t_2, t_1) = I_2 \tag{22}$$

$$\bar{e}(t_2, t_1) = E_2 \tag{23}$$

and these substituted in (4) and (6) give the initial conditions for the next arcing event. The sequence is then repeated according to table II.

If the current rupture is assumed to be abrupt, the procedure can be simplified to the form of table III.

It will be noticed in the above tabulation that the initial voltage $E_k$ for each event (following restrike) is merely the applied normal frequency voltage at that instant; for the restriking of the arc places the capacitance directly across the applied voltage and we are neglecting the arc drop.

Of great interest is the possibility of discontinuing the high-voltage transient following a restrike near the peak of the voltage transient.

The dangerous component of the voltage transient is the term containing $I_k$ in equation 11, and therefore if $I_k = 0$ this term vanishes. But

$$I_k = -I_{k-1} \cos w\,(t_k - t_{k-1}) + \frac{E_{k-1}}{wL} \sin w\,(t_k - t_{k-1}) \qquad (24)$$

and thus the condition $I_k = 0$ is satisfied by

$$\tan w\,(t_k - t_{k-1}) = \frac{wLI_{k-1}}{E_{k-1}} = \frac{w}{\omega}\,\frac{\omega LI_{k-1}}{E_{k-1}} \qquad (25)$$

Now $w/\omega$ is usually large (say of the order 100 to 1) and therefore even for small values of $I_{k-1}$ equation 25 shows that the tan $w(t_k - T_{k-1})$ is large, so that the condition corresponds to a restrike near the peak of the voltage oscillation. A number of oscillograms illustrating this condition have been given in the text. Of course, tests with d-c are particularly favorable to this condition.

# The Enlarging Concept of Engineering

By VLADIMIR KARAPETOFF, Fellow AIEE

IN proportion as the concept of "laws of nature" grows larger to include individual human behavior and group action, the engineer is called upon to apply his time-tested methods to broader problems of state and country. The usual definition of engineering, as the science and art of applying laws of nature to human needs, still holds; only the laws of nature cannot be limited any longer to those of levers and expanding steam. Sales engineering and works management have been the two windows through which the mechanistically minded engineer has been made to see broader aspects of his profession, involving fickle human will, prejudices, and emotional response. It is true that these propensities cannot yet be predicted with the same accuracy as the strength of a beam or the behavior of an electric generator, but the engineer has always included a lot of intuitive art (horse sense) as a part of his professional make-up anyway. As the laws of human behavior become better known we may expect an ever increasing influence of properly trained engineers upon our political, economic, and social life.

A person who can play fragments of half a dozen pieces on the piano in a crude fashion is not a musician worthy of that name. The new engineer whom I am picturing is not a man who barely has had short courses in elementary psychology and economics, in addition to his big courses in machine design and laboratories. My plea is primarily for a longer college course, following the example of the professions of law and medicine. Our nation must be awakened to the great possibilities of scientific planning and systematic gradual realization of an all-embracing economic and social program, a plan that would carry us as little scathed as possible beyond the present unrest and uncertainties. The men and women who know what is needed and what is possible to accomplish to save this country from a chaos do not yet call themselves engineers. They may be historians, sociologists, economists, psychologists, or what not. But once they are called upon to lay down definite plans and to execute them, they become engineers, for they will have to employ practically the same rigid methods of design and management as those used in building a mammoth bridge or running a huge automobile plant. Thus, these human engineers of the new kind should have considerable general engineering ability and training, and at the same time be experts in one of the lines of "social engineering." An analogy with a medical specialist readily suggests itself.

I am unalterably opposed to anything superficial in engineering training in colleges, for with the present spread of popular information superficial knowledge is readily picked up from the daily and weekly press and by simply keeping one's eyes open. The ranks of the new engineers should not be filled from among so-called practical youths who cannot master mathematics or mechanics. The social engineer has to be even more analytical than his older mechanistically inclined colleague, for he is to apply himself to much more difficult problems and to problems whose solutions cannot be looked up in a handbook like the size of an I-beam. The only choice left is to lengthen the course of training to five or even six years. No student should be allowed to specialize for at least three years; during these years he should be imbued with the general point of view of an engineer, using as illustrations some simple problems taken from two or three usual domains of engineering activity. This means a training both in the fundamental sciences and in applied situations. From there on, the attention devoted to one or two chosen specialties should be gradually increased, and the time devoted to the other engineering subjects tapered down.

Social engineers alone can convert our present society into a properly subdivided and inwardly correlated politico-economic unit wherein each of us could move in his proper sphere without dominating others or being dominated by them. My appeal is for such social engineers.

From an address delivered by the author before the trustees, the faculty, and invited guests of the Polytechnic Institute of Brooklyn, at the University Club, New York, N. Y., June 16, 1937, on the occasion of granting him an honorary degree of doctor of science. Doctor Karapetoff is professor of electrical engineering at Cornell University, Ithaca, N. Y.

# Network-Analyzer Solution of Multiple Unbalances

By EDWARD W. KIMBARK
MEMBER AIEE

SOME EXAMPLES of multiple unbalances on a 3-phase network are:

1. Two or more unsymmetrical short circuits at different points of a network. Faults involving more than one circuit are not unusual on multicircuit lines, and simultaneous faults sometimes occur even at geographically separated points, especially on systems grounded through high impedance. System stability or operation of relays during such faults may require investigation.
2. A short circuit partially cleared by the blowing of a fuse.
3. A short circuit on a line having series capacitors, the capacitors in the faulted conductor being short circuited by protective devices.
4. Two or more single-phase or unbalanced loads.

The solution for current, voltage, and power at specified points of such a network containing any one of the multiple unbalances listed above is greatly facilitated by the use of a network analyzer (a-c calculating board). The a-c board is a much more powerful tool than the d-c board for solving multiple unbalances, and its use for this purpose saves even more time and labor than it does in solving single unbalances. The technique of its use is of interest at this time in view of the increasing use and importance of network analyzers.

A number of different methods are available for the network-analyzer solution of multiple unbalances. The method to be preferred in any particular case depends on the nature of the problem to be solved and on the equipment available.

The methods may be broadly classified into symmetrical component methods and 3-phase methods. Several symmetrical component methods, which have been published,[1,2,3] will be summarized and compared with each other and with the 3-phase methods. The latter will be described in detail.

## I. Symmetrical-Component Methods

In the symmetrical component methods the 3-phase network is represented on the calculating board by its sequence networks, set up either together or in succession.

### A. Equivalent-Circuit Method

This method was devised by Miss Clarke[1] for the case of 2 simultaneous faults, and is suitable for all types of double unbalance. The 2 faults (or double unbalance) are represented by a 3-terminal equivalent circuit connected to the positive-sequence network at the 2 points of fault and the neutral point. In some cases the equivalent circuit must contain an adjustable source of voltage. The impedances of the equivalent circuit depend on the impedances of the zero-sequence and negative-sequence networks measured from the points of fault and on the types of faults or of unbalance.

The determination of the impedances of the equivalent circuit requires algebraic work which, however, has been done and tabulated for combinations of 2 short circuits. The equivalent circuit must be modified if any change occurs in the zero- or negative-sequence networks, as, for example, by the opening of a line; but it is not affected by swinging of the generators except in so far as this may require readjustment of the electromotive force of the equivalent circuit. The equivalent-circuit method has the advantage of requiring only one sequence network to be set up at a time, thus permitting a large power system to be represented with the minimum number of phase shifters and impedance units. It is particularly good for problems, such as stability studies, in which only the positive-sequence quantities are of interest. If zero- or negative-sequence quantities are desired the respective networks must be solved separately. The method is limited to two simultaneous faults (or a double unbalance).

### B. Shunt Method

This method, which was suggested by Professor W. V. Lyon,[2] is similar to the preceding one except that each fault is represented by a single impedance connected in shunt with the positive-sequence network at the point of fault. The impedance of each shunt depends not only on the impedances of the zero- and negative-sequence networks and on the types of all the faults, but also on the impedances of the positive-sequence networks and on the ratio of the open-circuit positive-sequence voltages at the points of fault. As a result, the impedances of the fault shunts are affected by swinging of generators if the ratio of open-circuit fault voltages is affected thereby, as it generally is. Professor Lyon has worked out expressions for the values of the shunts representing 2 faults. The method can be extended to any number of simultaneous faults by suitable algebraic determination of the values of the shunts.

### C. Connection Method

This method requires all 3 sequence networks to be set up at the same time, and is therefore limited to a smaller system than are the 2 preceding methods. Any number of simultaneous short circuits or open circuits or both may be represented by suitable interconnections of the sequence networks as has been customary for representing single short circuits, except that in some cases the connections must be made through insulating transformers or through phase converters. The phase converter is any device

A paper recommended for publication by the AIEE committee on power transmission and distribution. Manuscript submitted September 9, 1937; released for publication October 8, 1937.

E. W. Kimbark is assistant professor of electrical engineering at the Polytechnic Institute of Brooklyn, Brooklyn, N. Y. This paper is based on a thesis submitted in partial fulfillment of the requirements for the degree of doctor of science, Massachusetts Institute of Technology, 1937.

1. For all numbered references, see list at end of paper.

which either automatically or by manual adjustment satisfies the conditions that its terminal voltages be exclusively of positive sequence and that its line currents be exclusively of negative sequence. A device of this kind, employing an induction machine as suggested in reference 3, has been successfully used with the Massachusetts Institute of Technology network analyzer. The connections for representing 2 simultaneous line-to-ground faults, one on phase $a$, the other on phase $b$, are shown in figure 1. The interconnections are not affected by changes

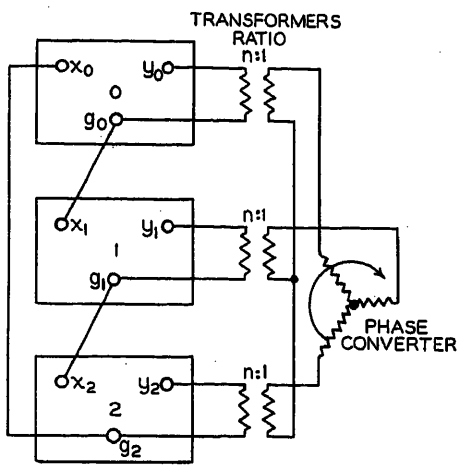

**Figure 1. Connections between the sequence networks for representing simultaneous AG-BG short circuits**

in the system, such as opening or closing of lines or swinging of generators, except in so far as these changes may necessitate readjustment of the phase converter, if one is used. This method dispenses with impedance measurements and the calculation required in the previous 2 methods for determining the fault shunts or the equivalent circuit, and is therefore more convenient if the size of system permits its use, particularly if zero- and negative-sequence quantitites are to be read. In case of simultaneous faults not all having the same phase of symmetry, the necessity for using a phase converter, which is not now standard equipment of any network analyzer, may be regarded as a disadvantage of the method.

## II. Three-Phase Methods

Although it has been customary to use the method of symmetrical components for fault studies on 3-phase networks, it is possible and often preferable to use either the phase quantities directly or substituted variables other than symmetrical components. This is particularly true when the values of phase currents and voltages are wanted, as in studies of relay operation. Two methods utilizing 3-phase set-ups will be described, both of which require the assumption that the positive- and negative-sequence networks are identical except as to generated electromotive forces, but neither of which requires the zero-sequence network to be like the positive- or negative-sequence networks. A method which did so restrict the zero-sequence network would not be of much value for representing a 3-phase power system, because of the great difference between the zero- and positive-sequence impedance of transmission lines, and because of the effects of various transformer connections.

The positive- and negative-sequence networks are, of course, identical except for the effects of polyphase rotating machinery, generators in particular. It is pertinent, therefore, to inquire as to the difference between the positive- and negative-sequence impedances of generators. Either the transient reactance ($x_d'$) or the subtransient reactance ($x_d''$) is use for the positive-sequence impedance of synchronous machines in fault studies, depending on how soon after the occurrence of the fault is the instant for which the fault currents are wanted. The following values of the ratios of negative-sequence reactance $x_2$ to transient and subtransient positive-sequence reactances are averaged from test results published by Wright.[4]

| Type of Machine | $x_2/x_d'$ | $x_2/x_d''$ |
|---|---|---|
| Round-rotor turbogenerators | 0.64 | 1.00 |
| Salient-pole machines with dampers | 0.64 | 0.96 |
| Salient-pole machines without dampers | 1.50 | 1.50 |

These ratios range from about 2/3 to 3/2; hence it would seem that in many cases the assumption that $Z_1 = Z_2$ would not be too bad, especially when it is considered that there are nearly always transformers and lines between the generators and the faults.

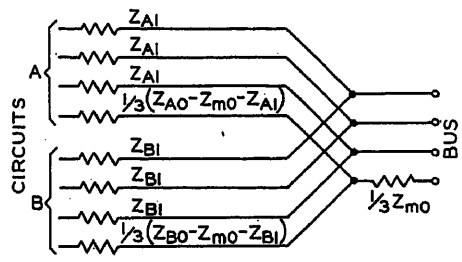

**Figure 2. Representation of 2 transmission lines with zero-sequence mutual impedance, connected to the same bus at the right-hand end, as represented in the 3-phase and neutral method**

In cases in which the difference between positive- and negative-sequence impedance may be of importance, it may be taken into account by a method described later in this paper.

### A. Three-Phase and Neutral Method

This method was independently devised and used on the Westinghouse and Massachusetts Institute of Technology network analyzers.

*1. Representation of System.* The power system is represented as a 3-phase 4-wire circuit. The 3 line conductors of each branch have impedances equal to the positive- or negative-sequence impedance $Z_1$ of the branch, while the impedance $Z_n$ of the neutral conductor is given by $Z_n = \frac{1}{3}(Z_0 - Z_1)$. Positive- and negative-sequence components of current are confined to the line wires and therefore produce the correct $IZ$ drops in the line-to-neutral voltage. If zero-sequence components of current are present, they have the same value $I_0$ in each line conductor. Assuming that the sum of these components, $3I_0$, returns in the neutral conductor, the drop in line-to-

neutral voltage produced in the branch by the zero-sequence current is the same for each phase and has the magnitude

$$I_0Z_1 + 3I_0 \times \frac{1}{3}(Z_0 - Z_1) = I_0Z_0$$

which is correct. Zero-sequence mutual impedance $Z_{m0}$ between 2 parallel transmission lines connected to the same bus at one end may be represented as shown in figure 2. Here the drop in line-to-neutral voltage of circuit $A$ is:

$$I_{A0}Z_{A1} + 3I_{A0} \times \frac{1}{3}(Z_{A0} - Z_{m0} - Z_{A1}) + (3I_{A0} + 3I_{B0}) \times \frac{1}{3}Z_{m0} = I_{A0}Z_{A0} + I_{B0}Z_{m0}$$

Shunt capacitance of lines, if appreciable, may be represented as in figure 3, in which $C_1$ is the positive-sequence capacitance and $C_n$ has the value $3\,C_0C_1/(C_1 - C_0)$, where $C_0$ is the zero-sequence capacitance.

The potential drops due to zero-sequence current are not correct unless the zero-sequence currents actually return in the neutral wire, as assumed. That is, in every branch of the 3-phase network, we must have

$$I_a + I_b + I_c + I_n = 0$$

or

$$I_n = -(I_a + I_b + I_c) = -3I_0$$

This requirement is automatically satisfied in all radial branches of the 3-phase network. If the network has one or more closed loops, the currents in general will not satisfy this requirement automatically but they may be forced to do so by inserting "forcing transformers" in series with one or more branches. Figure 4 shows several alternative arrangements of forcing transformers; scheme (*d*) is perhaps the most practical. The number of banks of forcing transformers is, in general, equal to the number of independent loops in the 3-phase network, but in some networks the impedances are so related that correct current distribution is obtained even though fewer or no banks are used. If there should be doubt in a specific case as to the proper number and location of forcing transformers, the best procedure would be to set up the network without forcing transformers and to measure the line and neutral currents in rectangular form in several branches of the network. The sum of the 3 line currents should then be compared with the neutral current. If the agreement should not be satisfactory, forcing transformers should be inserted, and the check readings should again be taken.

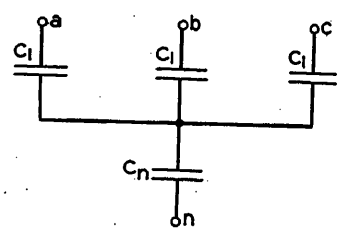

**Figure 3. Representation of shunt capacitance in the 3-phase and neutral method**

Generator voltages are represented by balanced 3-phase electromotive forces. Three phase-shifters connected in $Y$ may be used to represent either grounded or ungrounded generators; or 2 phase-shifters connected in $V$, to represent ungrounded generators. Phase-shifters with 3-phase output are not suitable because the internal impedance drops due to unbalanced loads produce unbalanced terminal voltages.

The terminal voltages of the phase shifters may be purposely unbalanced (as suggested by Professor L. F. Woodruff) to represent the effect of the difference between the positive- and negative-sequence impedances of a generator. To do so, the generator phase currents are measured with balanced phase-shifter voltage, and the negative-sequence current $I_2$ and the voltage $V_2' = I_2\,(Z_1 - Z_2)$ are computed from them. The phase-shifter terminal voltages are then changed by the addition of voltages $V_2'$, $aV_2'$, and $a^2V_2'$ to phases $a$, $b$, and $c$, respectively.

Transformer banks in the power system may be represented on the network analyzer by actual transformer banks or, in some cases, by simple series impedances, as shown in figure 5. The representation of $\Delta$-$Y$ banks by series impedances does not directly give the correct currents and voltages on the side of the transformer away from the fault (this is also true of symmetrical-component methods), and cannot be used in case of simultaneous faults on opposite sides of such banks.

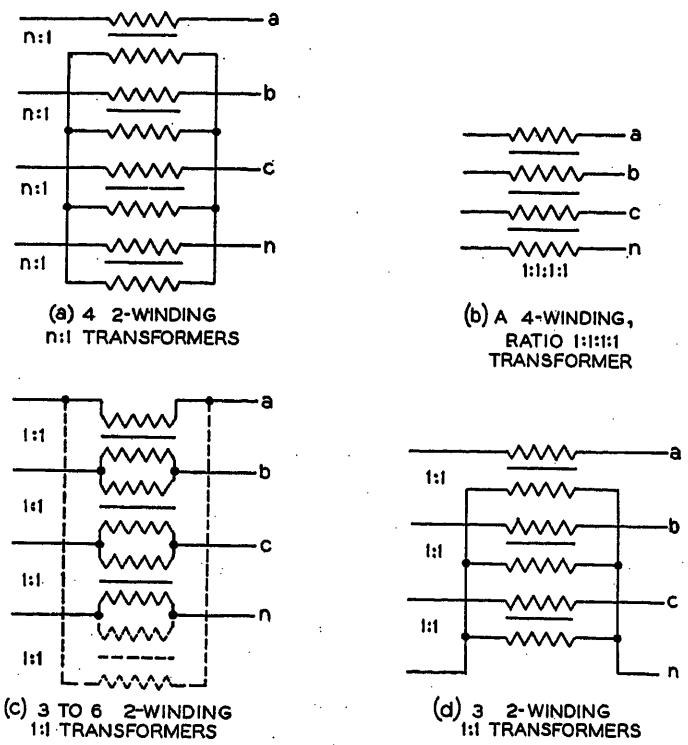

**Figure 4. Connections of forcing transformers for use in the 3-phase and neutral method**

*2. Representation of Unbalance.* Faults are applied by making the actual fault connection, connections to ground being made to the corresponding point of the neutral network. Any number of faults, on any phases, may be ap-

plied simultaneously without causing complications. Unbalanced loads or unbalanced series impedances are represented just as simply.

*3. Measurements.* The following quantities can be measured directly: line currents, residual current (in neutral), line-to-line voltages, line-to-ground voltages (measured line to neutral). Residual voltage can be read by the use of 3 potential transformers having their primary windings connected line-to-neutral and their secondary windings in series, or can be computed as the sum of the line-to-ground voltages. Positive-sequence and negative-sequence quantities are not so conveniently obtained, but they can be computed or measured by the same methods which can be used to obtain phase quantities from a symmetrical-component representation.

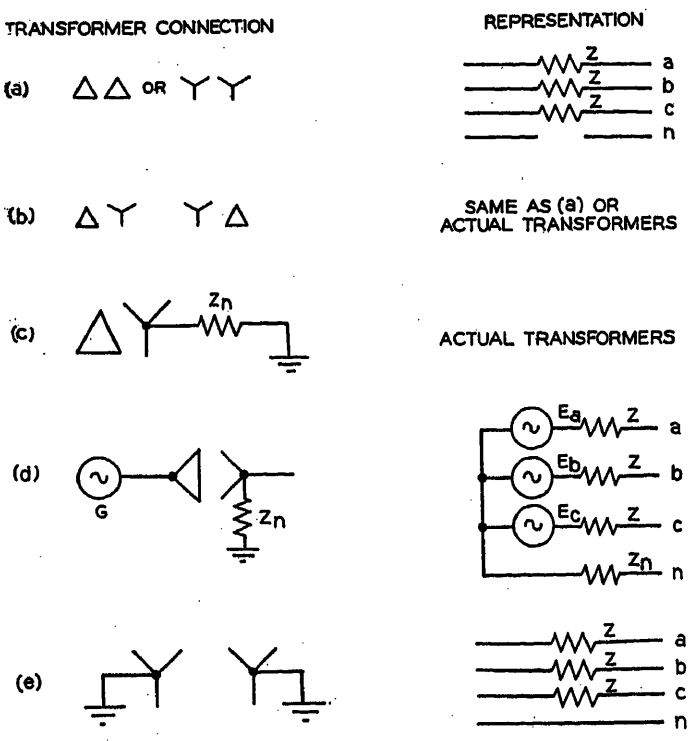

**Figure 5. Representation of transformer banks in the 3-phase and neutral method**

*4. Advantages and Disadvantages.* This method requires 4 impedance units per branch of the one-line system diagram, and thus is limited to smaller systems than are the equivalent-circuit and shunt methods. It requires 3 phase-shifters per generator, thus limiting the number of generators which can be represented and giving more trouble in adjusting the generator phase angles or outputs. Forcing transformers are required in many cases to give correct current distribution in the network. It is necessary to assume that the negative-sequence impedance of each branch is equal to the positive-sequence impedance.

On the other hand, the representation of simultaneous faults and unbalances of any kind is extremely simple. Phase and residual currents, line-to-line and line-to-neutral voltages can be read directly.

The best field of application is to networks of small or medium size and principally at one voltage, with only one or two equivalent generators, and to problems (such as relay studies) in which phase quantities are required.

### B. Three-Phase and Zero-Sequence Method

This method differs from the preceding one in that zero-sequence current and voltage are excluded from the 3-phase network and confined to a separate network. The fault connections and the methods of measurement are not quite as simple as in the method just described, but the correct current distribution is obtained without recourse to forcing transformers.

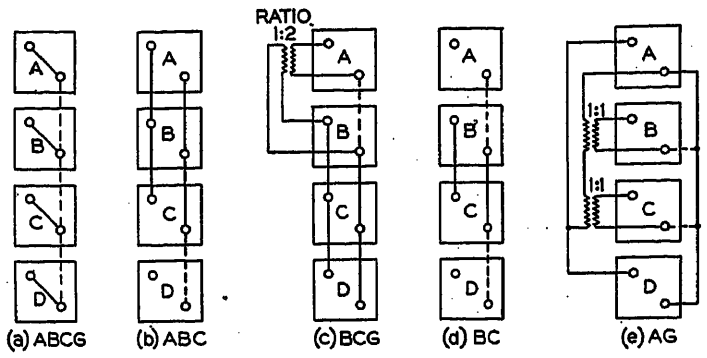

**Figure 6. Connections between the substitute networks for representing various types of short circuits, 3-phase and zero-sequence method**

The theory of the method is explained in the appendix.

Four substitute networks, designated as $A$, $B$, $C$, and $D$, are set up on the network analyzer. Networks $A$, $B$, and $C$ have in each branch an impedance equal to the positive- (or negative-) sequence impedance, while network $D$ (which might be termed the zero-sequence network) has an impedance equal to one-third the zero-sequence impedance of the corresponding branch of the power system. Expressed symbolically, $Z_A = Z_B = Z_C = Z_1 = Z_2$, and $Z_D = \frac{1}{3} Z_0$. Networks $A$, $B$, $C$ contain 3-phase electromotive forces, but network $D$ has none. The currents and voltages in networks $A$, $B$, and $C$ are the phase quantities minus their zero-sequence components. The current and voltage in network $D$ are related to the zero-sequence quantities as follows:

$$I_D = -3I_0 \quad \text{and} \quad V_D = -V_0$$

The connections between the substitute networks for representing various kinds of short circuits are derived in the appendix and are shown in figure 6. The dotted lines indicate connections which are put in merely for convenience in measuring line-to-line voltages. Note that the connections for faults not involving ground are, as in the preceding method, the actual fault connections; whereas for the $BCG$ and $AG$ faults direct connections are made in accord with the actual fault connections (regarding network $D$ as the ground), and are supplem

by connections through transformers to the unfaulted phases. Faults on phases other than those for which connections are given are represented by similar connections with an appropriate interchange of networks $A$, $B$, and $C$. Simultaneous faults are represented by making the connections for each fault just as for a single fault.

After having made the appropriate fault connections, the following quantities may be measured directly as indicated: line-to-line voltages, between corresponding points of networks $A$, $B$, $C$; line-to-ground voltages, between corresponding points of network $A$, $B$, or $C$ and network $D$; residual current, in network $D$; zero-sequence voltage in network $D$. Furthermore, the phase currents may be read by the use of a 3-to-1 current transformer with its primary winding plugged into network $D$ and its secondary winding connected to the measuring device in parallel with a cord plugged into the corresponding branch of the phase network. (See equations $A1$ to $A3$ of appendix.)

## C. Triple-Connection Method

This method, using a 3-phase and symmetrical-component representation, could be classified under either heading.

The procedure is as follows:

1. Set up each sequence network in triplicate, that is, set up 3 zero-sequence networks, 3 positive-sequence networks, and 3 negative-sequence networks. The 3 positive-sequence networks should differ from one another only in that the electromotive forces in any one of them are 120 degrees ahead of the corresponding electromotive forces in another and 120 degrees behind those of the third. Phase-shifters having a 3-phase output are suitable sources of the electromotive forces.

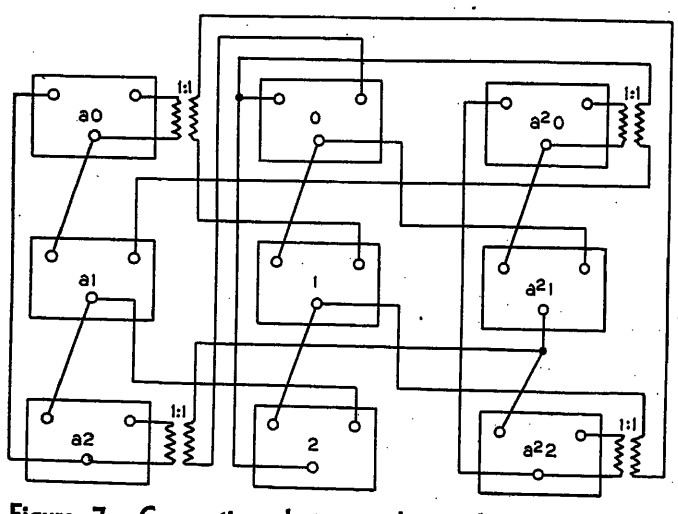

**Figure 7. Connections between the triple sequence networks for representing simultaneous AG-BG short circuits, triple-connection method**

2. At each point of fault make appropriate connections between the sequence networks to represent the given type of fault. These connections can be best understood by considering a particular case, such as simultaneous $AG$-$BG$ faults, figure 7. Let the current and voltage at the left-hand terminal of network 0 be $I_{x0}$ and $V_{x0}$, respectively, and at the right-hand terminal, $I_{y0}$ and $V_{y0}$. Then assume for the time being that the corresponding quantities of network $a0$ are $aI_{x0}$, $aV_{x0}$, $aI_{y0}$, and $aV_{y0}$, where $a = \angle 120°$, and that the corresponding quantities of network $a^20$ are $a^2I_{x0}$, $a^2V_{x0}$, $a^2I_{y0}$, and $a^2V_{y0}$, respectively; and similarly for the positive- and negative-sequence networks; that is, assume that all currents and voltages at the terminals of and within the networks of the left-hand column are equal in magnitude to, but 120 degrees ahead of, the corresponding currents and voltages of the middle column of networks, and that likewise the right-hand column is 120 degrees behind the middle column. These assumptions are justified by the fact the 3 columns are identical, except for the 120-degree phase displacement of the positive-sequence electromotive forces, and by the fact that the connections to be established between the networks have a cyclical symmetry. It will be recalled that the equations for the $AG$ fault at $x$ are:

$$I_{x0} = I_{x1} = I_{x2} \quad \text{and} \quad V_{x0} + V_{x1} + V_{x2} = 0 \tag{1}$$

which are satisfied by a series connection of the left-hand ($x$) terminals of networks 0, 1, and 2. Multiplying equation 1 by $a$ gives

$$aI_{x0} = aI_{x1} = aI_{x2} \quad \text{and} \quad aV_{x0} + aV_{x1} + aV_{x2} = 0 \tag{2}$$

which are satisfied by a series connection of the left-hand terminals of networks $a0$, $a1$, and $a2$. Similarly, multiplication of equation 1 by $a^2$ indicates a series connection of the left-hand terminals of networks $a^20$, $a^21$, and $a^22$. The equations for the $BG$ fault at $y$ are:

$$I_{y0} = a^2I_{y1} = aI_{y2} \text{ and } V_{y0} + a^2V_{y1} + aV_{y2} = 0 \tag{3}$$

and are satisfied by a series connection of the right-hand ($y$) terminals of networks 0, $a^21$, and $a2$. Multiplication of equation 3 by $a$ gives

$$aI_{y0} = I_{y1} = a^2I_{y2} \quad \text{and} \quad aV_{y0} + V_{y1} + a^2V_{y2} = 0 \tag{4}$$

which are satisfied by a series connection of the right-hand terminals of networks $a0$, 1, and $a^22$. Likewise multiplication of equation 3 by $a^2$ points to a series connection of networks $a^20$, $a1$, and 2. In making these connections, which are shown in figure 7, a sufficient number of insulating transformers must be used (in this case at least 4).

In every case, a fault which is symmetrical with respect to phase $a$ is represented by connections between networks in the same column, whereas a fault symmetrical with respect to phase $b$ or phase $c$ is represented by diagonal connections touching a different column in each row.

3. Read the sequence currents and voltages in any branches where they are wanted. The zero-sequence quantities are read in network 0, positive-sequence in network 1, and negative-sequence in network 2. It is also possible to read $a^2$ times the positive-sequence quantities in network $a^21$, $a$ times the negative-sequence quantities in network $a2$, etc. Then the phase quantities may be readily calculated by adding the proper components:

$$I_a = I_0 + I_1 + I_2$$

$$I_b = I_0 + a^2I_1 + aI_2, \text{ etc.}$$

Or, better yet, by combining the proper components through instrument transformers, the phase quantities can be read directly. Thus, $I_b$ can be obtained by paralleling the secondary windings of 3 current transformers, the primary windings of which are plugged into corresponding branches of networks 0, $a^21$, and $a2$; similarly $V_b$ can be obtained by connecting in series the secondary windings of 3 potential transformers. A switching arrangement might be built to facilitate rapid successive reading of the several phase quantities. The best arrangement appears to be to do all the measuring in only 3 networks (say networks 0, 1, 2) and to interchange 2 of these networks with others in the same row. To be more specific, to read $Ia$, current jacks are plugged into networks 0, 1, and 2, and the sum, $I_a = I_0 + I_1 + I_2$, is read. Then to obtain $I_b$, the jacks are left in position, network 1 without its electromotive forces is interchanged with network $a^21$ without its electromotive forces, and network 2 is interchanged with network $a2$. Or, to avoid the switching of the positive-sequence networks

with respect to their power sources, it would be better to interchange network 0 with $a0$, and network 2 with $a^2 2$, and to read the sum $aI_0 + I_1 + a^2 I_2 = aI_b$, which by a suitable rotation of reference axes in the measuring instrument may be read as $I_b$.

The triple connection method, like the single connection method, is applicable to any number of simultaneous faults, and does not require that the negative-sequence impedances equal the positive-sequence impedances. Unlike the single connection method, it does not require a phase converter for representing faults not symmetrical

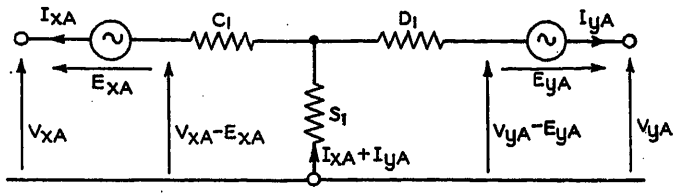

**Figure 8. Equivalent T circuit to which network A (3-phase and zero-sequence method) may be reduced, retaining the 2 points of fault and the neutral point. Networks B and C can be represented similarly**

with respect to phase $a$. Its principal disadvantage is the excessive number of impedance units required (approximately 9 units for each branch of the one-line system diagram), which makes the method impractical except for relatively small systems. An advantage is the possibility of directly reading the phase currents and voltages as well as their symmetrical components. The required number of impedance units can be decreased without losing the advantage of direct reading of phase quantities by setting up only three of the networks complete and the other six in reduced form (equivalent $T$ or $\pi$ in case of 2 simultaneous faults or a double unbalance). Readings are taken in the 3 complete networks, two of which are interchanged with reduced networks by a suitable switching device to read phase $b$ or $c$ quantities. The saving in number of impedance units entails the work of determining and setting up equivalent reduced circuits for each fault or system condition. If the direct reading of phase quantities be dispensed with, only one complete network need be set up at a time, the other eight being represented by equivalent circuits. However, in this case the equivalent circuit method might better be used.

## Conclusion

Some new methods have been presented, and some older ones summarized and compared, for solving networks with multiple unbalances by use of a network analyzer. For stability studies, especially on large systems, with 2 simultaneous faults, the equivalent circuit method appears to be the most suitable. For the rare case of more than 2 faults the shunt method may be employed. For studies of relay operation on smaller systems and in which swinging of generators is not an important factor, the 3-phase methods are best. Of these the 3-phase-and-neutral method is usually the simpler. However, on a network in which a large number of forcing transformers would be required to secure correct current distribution it appears simpler to use the 3-phase and zero-sequence method, in which transformers are used in the connections representing faults instead of as forcing transformers. In other problems, the network analyzer operator can select whatever method may appear best suited to the problem at hand.

## Appendix

### Theory of 3-Phase and Zero-Sequence Method and Proof of Connections for Representing Short Circuits

The method is based on a substitution of variables analogous to the one employed in the method of symmetrical components. Let $I_a, I_b, I_c$ be the line currents and $V_a$, $V_b$, $V_c$ the voltages to ground of the 3 conductors of the 3-phase system. Let new variables $I_A$, $I_B$, $I_C$, $I_D$ and $V_A$, $V_B$, $V_C$, $V_D$, defined as follows be introduced:

$$I_a = I_A - \frac{1}{3} I_D \tag{A1}$$

$$I_b = I_B - \frac{1}{3} I_D \tag{A2}$$

$$I_c = I_C - \frac{1}{3} I_D \tag{A3}$$

in which

$$I_A + I_B + I_C = 0 \tag{A4}$$

Also let

$$V_a = V_A - V_D \tag{A5}$$

$$V_b = V_B - V_D \tag{A6}$$

$$V_c = V_C - V_D \tag{A7}$$

in which

$$V_A + V_B + V_C = 0 \tag{A8}$$

The inverse transformations are as follows:

$$I_A = \frac{1}{3}(2I_a - I_b - I_c) \tag{A9}$$

$$I_B = \frac{1}{3}(2I_b - I_c - I_a) \tag{A10}$$

$$I_C = \frac{1}{3}(2I_c - I_a - I_b) \tag{A11}$$

$$I_D = -(I_a + I_b + I_c) \tag{A12}$$

$$V_A = \frac{1}{3}(2V_a - V_b - V_c) \tag{A13}$$

$$V_B = \frac{1}{3}(2V_b - V_c - V_a) \tag{A14}$$

$$V_C = \frac{1}{3}(2V_c - V_a - V_b) \tag{A15}$$

$$V_D = -\frac{1}{3}(V_a + V_b + V_c) \tag{A16}$$

Note that four new currents, $I_A$, $I_B$, $I_C$, $I_D$, are substituted for 3 old currents $I_a$, $I_b$, $I_c$ but that only 3 of the 4 are independent, as they are subject to the restriction expressed in equation $A4$. The

same remark applies to the substitution of voltages. The $D$ quantities are related to the zero-sequence quantities as follows:

$$I_D = -3I_0 \quad \text{and} \quad V_D = -V_0 \tag{A17}$$

Therefore the $A$, $B$, $C$ quantities are the phase quantities minus their zero-sequence components.

Let $I_A$ and $V_A$ be associated with a network $A$, $I_B$, and $V_B$ with network $B$, etc. The connections between networks $A$, $B$, $C$, and $D$ for representing various kinds of faults will be determined, but before doing so 2 general relations will be noted. First, as may be shown readily, the total vector power of corresponding branches of the substitute networks ($A$, $B$, $C$, $D$) is equal to the total vector power in the corresponding branch of the original 3-phase power network.

$$\overline{V}_A I_A + \overline{V}_B I_B + \overline{V}_C I_C + \overline{V}_D I_D = \overline{V}_a I_a + \overline{V}_b I_b + \overline{V}_c I_c \tag{A18}$$

(The bars over the $V$'s in this equation denote conjugates.) A relation of this kind—one side of the equation may be multiplied by a constant, however—must be fulfilled if a fault is to be represented by a connection between the substitute networks. For, if the fault has no impedance, the vector power in the fault branch is zero; if connections are made between the networks, either directly or through ideal transformers, the total vector power leaving the networks at the points of connection is likewise zero.

The second general relation concerns the exclusion of zero-sequence current and voltage from networks $A$, $B$, $C$ in accordance with equations $A4$ and $A8$. Consider the case of 2 simultaneous faults. Each of the networks $A$, $B$, $C$ may be reduced to an equivalent $T$ (figure 8), retaining the 2 points of fault and the ground or neutral point. These $T$'s, like the equivalent $T$ of the positive-sequence network, each contain 2 equivalent electromotive forces, denoted by $E_x$ and $E_y$, equal to the voltage at the points of fault before occurrence of the faults. The following equations express relations between fault currents ($I_x$ and $I_y$) and fault voltages ($V_x$ and $V_y$) of each network:

$$E_{xA} - V_{xA} = (C_1 + S_1) I_{xA} + S_1 I_{yA} \tag{A19}$$

$$E_{xB} - V_{xB} = (C_1 + S_1) I_{xB} + S_1 I_{yB} \tag{A20}$$

$$E_{xC} - V_{xC} = (C_1 + S_1) I_{xC} + S_1 I_{yC} \tag{A21}$$

$$E_{yA} - V_{yA} = (D_1 + S_1) I_{yA} + S_1 I_{xA} \tag{A22}$$

$$E_{yB} - V_{yB} = (D_1 + S_1) I_{yB} + S_1 I_{xB} \tag{A23}$$

$$E_{yC} - V_{yC} = (D_1 + S_1) I_{yC} + S_1 I_{xC} \tag{A24}$$

where $C_1$, $D_1$, and $S_1$ are impedances of the equivalent $T$, which are the same for all 3 networks. Adding each group of three equations gives:

$$\Sigma E_x - \Sigma V_x = (C_1 + S_1)\Sigma I_x + S_1 \Sigma I_y \tag{A25}$$

$$\Sigma E_y - \Sigma V_y = (D_1 + S_1)\Sigma I_y + S_1 \Sigma I_x \tag{A26}$$

where

$$\Sigma E_x = E_{xA} + E_{xB} + E_{xC}$$
$$\Sigma I_x = I_{xA} + I_{xB} + I_{xC}, \text{ etc.}$$

Since the networks contain only balanced electromotive forces (or at least electromotive forces having no zero-sequence components), $\Sigma E_x = 0$ and $\Sigma E_y = 0$. Therefore, unless one of the impedances should be infinite, if $\Sigma I_x = 0$ and $\Sigma I_y = 0$, then it follows that $\Sigma V_x = 0$ and $\Sigma V_y = 0$; or, more generally, if either $\Sigma V_x = 0$ or $\Sigma I_x = 0$ and if either $\Sigma V_y = 0$ or $\Sigma I_y = 0$, then all 4 quantities, $\Sigma V_x$, $\Sigma V_y$, $\Sigma I_x$, and $\Sigma I_y$, are zero. Although the demonstration has been given for the case of 2 faults, similar demonstrations can be given for one fault, or for any number of faults. As a result of such demonstrations it may be reasoned that the connections representing a fault must be of such nature as to insure either that $\Sigma V = 0$ or that $\Sigma I = 0$; if either of these conditions is fulfilled at every fault (not necessarily the same condition at every fault), it follows that both $\Sigma V = 0$ and $\Sigma I = 0$ at all faults and hence also throughout networks $A$, $B$, $C$.

Any connection between the 4 substitute networks may be described by 4 equations. For the connections to correctly represent a given type of fault, 3 of the equations must be derived from the relations between phase currents and voltages for the fault in question (table I of reference 1); the fourth must be either $\Sigma V = 0$ or $\Sigma I = 0$. The connections for representing various single faults (figure 6) are proven correct as follows:

AG FAULT

Relations of phase quantities: $V_a = 0, I_b = 0, I_c = 0$. Relations between substituted quantities satisfied by the connections:

$$V_A = V_D \qquad V_A + V_B + V_C = 0 \qquad I_B = I_C = I_A + I_D$$

Proof that the connections represent the fault: Since $V_A + V_B + V_C = 0$, it follows that $I_A + I_B + I_C = 0$. Substitute in the latter expression $I_C = I_B$ and $I_A = I_B - I_D$, obtaining $I_B - \frac{1}{3} I_D = 0$, or $I_b = 0$. By a similar process, obtain $I_C - \frac{1}{3} I_D = 0$, or $I_c = 0$. $V_A - V_D = 0$ is equivalent to $V_a = 0$.

BCG FAULT

Relations of phase quantities: $I_a = 0, V_b = 0, V_c = 0$. Relations between substituted quantities satisfied by the connections:

$$-\frac{1}{2} V_A = V_B = V_C = V_D \text{ and } -2I_A + I_B + I_C + I_D = 0$$

Proof that the connections represent the fault: From the voltage relation, $-\frac{1}{2} V_A = V_B = V_C$, it may be shown that $V_A + V_B + V_C = 0$, from which it follows that $I_A + I_B + I_C = 0$. Subtracting $I_A + I_B + I_C = 0$ from $-2I_A + I_B + I_C + I_D = 0$ gives $-3I_A + I_D = 0$, or $I_A - \frac{1}{3} I_D = 0$, or $I_a = 0$. From $V_B = V_C = V_D$, we obtain $V_B - V_D = 0$ and $V_C - V_D = 0$, or $V_b = 0$ and $V_c = 0$.

BC FAULT

Relations of phase quantities: $I_a = 0, I_b + I_c = 0, V_b = V_c$. Relations between substituted quantities satisfied by the connections: $V_B = V_C, I_B + I_C = 0, I_A = 0, I_D = 0$. Proof that the connections represent the fault: Since $I_D = 0$, $I_A - \frac{1}{3} I_D = 0$ or $I_a = 0$.

$$I_B + I_C = (I_B - \frac{1}{3} I_D) + (I_C - \frac{1}{3} I_D) = I_b + I_c = 0$$

Since $V_B = V_C$, $V_B - V_D = V_C - V_D$ or $V_b = V_c$. The connections also satisfy $I_A + I_B + I_C = 0$.

ABC FAULT

Relations of phase quantities: $I_a + I_b + I_c = 0, V_a = V_b = V_c$. Relations satisfied by connections: $I_A + I_B + I_C = 0, I_D = 0, V_A = V_B = V_C$.

ABCG FAULT

Relations of phase quantities: $V_a = V_b = V_c = 0$. Relations satisfied by connections: $V_A = V_B = V_C = V_D = 0$.

# Modern Trolley-Coach Operation

By JAMES H. POLHEMUS

## Synopsis

This paper describes the operation of a modern trolley coach system. This system was installed one year ago with a single line and a few coaches. Now there are 7 lines in operation, the total route lengths exceeding 45 miles and requiring 40 coaches, each of which has a seating capacity of forty persons. The paper is generally divided into 2 parts, the first dealing with descriptions of the system and equipment, and the second part setting forth such experiences as have been gained in one year of operation.

ALTHOUGH there were earlier installations, the operation of modern trolley coaches may be said to date from 1928, when trolley coaches were put in operation in Salt Lake City. Systems were installed in more and more cities until today trolley coach operation is a factor in public transportation in 34 cities of the United States, not to mention the many European systems. It is the objective of this paper to discuss one of the most recently installed trolley coach systems, that of the Portland Traction Company in Portland, Oregon.

The Portland system consists of 45.5 miles of trolley coach line operating within the limits of the city and serving, together with 87.5 miles of street railway and 64.8 miles traversed by gasoline coaches, a population in excess of 300,000 people. Operation of trolley coaches started August 30, 1936, on the first line completed and additional lines were completed and put into operation until the contemplated program was consummated in May, 1937. The experiences throughout an over-all period of one year of operation are available although the completed system of 7 lines has been operating but 3 months. The system is now operating at the rate of about 385,000 coach miles per month and since the total mileage amounts to 3,300,000 coach miles in the 12 months of operation, the weighted average experience with this system amounts to about 8 or 9 months.

The overhead system is of the conventional 2-conductor type with the conductor tension at 3,000 pounds per conductor at 70 degrees Fahrenheit, with 100-foot spans in districts where coaches can operate at high speed. In the congested urban area, a tension of 2,000 pounds was used. The conductors are spaced 2 feet apart and the conductors nearest the curb are in general 12 feet from curb lines. A minimum clearance of 7 feet, 5 inches is maintained between inside conductors. The supporting structures are steel poles in the downtown areas and building pull-offs, if feasible, with wood poles in the outlying districts. The contact wire is 3/0 high-strength cadmium bronze alloy. On one of the 7 lines, the contact wire is round while wire on the remaining lines is grooved. Records are being kept to show the wearing ability of each, but it is yet too early to form even preliminary conclusions. The wire is lubricated with a light grade of mineral oil. The system operates with 600-volt direct current supplied by the affiliated Portland General Electric Company. Electric frogs of both shunt and series-operated type were installed and experience to date is in favor of the shunt type for system use as well as in the car barns. Porcelain strain insulators on pull-over wires have been found to be better than woodstick insulators when they can be located so that they will not be struck by a flying trolley. An interesting detail is that of passing tracks on which local coaches may draw up to the curb and allow express coaches to pass.

The Portland Traction Company now operates 140 trolley coaches over its 45 miles of trackless trolley routes. The coaches are 24 feet, 4½ inches over bumpers, 104 inches extreme width, weigh 20,400 pounds, and have seats for 40 passengers. The normal peak load is 60 passengers but 100 passengers have been carried during times of extraordinary traffic congestion. The rear axle ratio of 9.97 and 42-inch wheels at a motor speed of 3,360 rpm develop the maximum speed of 42 miles per hour. The traffic regulations permit a maximum speed of 35 miles per hour, requiring a motor speed of 2,800 rpm. Coaches are equipped with air brakes on all 4 wheels, all glass is shatterproof, and the windshield is cleaned with 4 pneumatically operated windshield wipers. Doors are operated by air engines under control of the operator and the exit door is also controlled by foot treadles. Auxiliary circuits, such as lighting, buzzer, door control, marker, tail and head lights, horn, and ventilating fans, are supplied with power from a 12-volt storage battery and generator system. The principal reason for the use of the 12-volt circuit is safety of passengers. Another reason is to insure continuity of lighting while the coach is passing under insulated spacers. One of the most unusual features of these coaches is that each is driven by a single motor. The motor has a rolled-steel frame and weighs 1,050 pounds. It has a one-hour rating of 125 horsepower and the output when accelerating on a grade is 225 horsepower. Four interpoles and low voltage per commutator bar provide freedom from flashovers. Other motor characteristics at the hourly rating of 125 horsepower are 600 volts, 173 amperes, 2,420 rpm, and 120 degrees centigrade rise by resistance. The maximum allowable motor speed is 4,000 rpm. The motor is self-ventilated and without covers. Radio choke coils are inserted in the trolley

A paper recommended for publication by the AIEE committee on transportation. Manuscript received October 7, 1937; released for publication October 15, 1937.

JAMES H. POLHEMUS is executive vice-president of the Portland Electric Power Company, Portland, Ore.

circuits on the roof of each coach to prevent the operation of the coach from interfering with radio reception.

The street cars replaced by electric coaches were operated by one man and there is no saving in the operators' wages per vehicle hour, but the increased speed has reduced the cost of operators' pay per vehicle mile.

In July, 1937, the average speed of all vehicles in the Portland system was 11.35 miles an hour, which is an increase of 11 per cent over the July, 1936, average speed of 10.23 miles an hour. A part of this is due to an increase

of speed of gas busses from 13.11 miles an hour to 13.40 miles an hour. The average speed of street cars decreased 4 per cent from 9.63 to 9.26 miles an hour, due to some of the higher-speed car lines being converted to electric coach lines. The average speed of electric coaches is 12.78 miles an hour and this is an increase of 23 per cent from the 10.35 miles an hour average speed of the street car lines that were changed to electric coach. Unloading at both ends has decreased standing time and has increased the average speed. At heavy loading points double ended loading likewise increases the average speed.

The rate of acceleration of electric coaches is 3.5 miles per hour per second and this is twice the rate of acceleration of the street cars replaced by the coaches. The free-running speed of the street cars was 27 miles an hour and of the electric coaches, 42 miles an hour. The coaches are operating on city streets where the speed is limited by law and the maximum possible speed is never used.

Accidents have been caused in some cases where automobiles, closely followed by street cars, have made sudden stops with the result that the auto was rammed by the street car. Electric coaches stop as fast as or faster than do automobiles and do not ram the rear end of motor vehicles that have suddenly stopped, but, if passengers are standing, rapid deceleration may throw some elderly person to the floor. Operators with a standing load of passengers at times must make a choice between a collision with another vehicle and the possibility of personal injuries to standing passengers. Some automobile drivers do not realize the rapid rate of acceleration of the electric coach and after passing to the left of an accelerating coach, reduce speed, cut to the right in front of the coach, and a collision results. In August 1937, street cars ran 4,299 miles per accident, electric coaches, 5,133 miles, and motor coaches ran 9,379, miles. Motor coaches run a smaller percentage of their miles in heavy traffic than electric coaches and street cars and have a lower exposure to accidents than street cars and electric coaches. The ratio of miles to accidents for electric coaches is increasing as the operators have more experience in operating these vehicles.

With respect to maintenance, tires are not purchased but are rented on a mileage basis. Traction company employes change tires that are worn or flat and the tire company dismounts the tires from the rims. Tire pressure is maintained by the traction company. Front tires on the coaches on a line which has many curves were found to wear rapidly and on these tires the normal pressure of 75 pounds was increased to 85 pounds and the tread wear was reduced.

New tires are averaging about 23,000 miles and retreads about 17,000 miles, a total of 40,000 miles to a casing. In a few instances a casing is given a second retread, thus giving a casing with 2 retreads a total life of 57,000 miles.

Maintenance of electrical equipment is confined largely to cleaning contacts on controls and cleaning motors. The voltage and current regulators on the 12-volt lighting and door control system must be checked frequently as these regulators are subject to burning if the contacts are not kept clean.

Inspection of all movable parts is done on a regular schedule and in this way maintenance is reduced and there is a greater reliability of service

Maintenance of bodies is confined, as yet, to tightening of screws and bolts. All metal bodies are not in need of much maintenance in the first year of their life and, except for adjustments of brakes and door operating engines, but little work is done on the bodies.

Accidents are with us always and there are at all times coaches in the shops for repairs necessitated by collisions. Both electric and gas welding reclaim parts that at first sight appear to be fit only for junk. Quick drying lacquers cover the new work and soon the coach is again on the street.

Lubrication of the conductor wires is accomplished by means of a truck with trolley busses and trolley poles mounted on a frame on the truck. The upper end of each pole carries a lubricator that is essentially a tank containing a lubricant with a wheel that has its upper rim on the conductor and the lower rim in the lubricant. The conductors are lubricated every 1,500 shoe passes. Much work on the overhead was not completed when the coaches were placed in operation and until this has been done no regular inspection of the overhead will be made. Many poles and anchors were set in damp soil and it has been necessary to retension conductors and brail wires. Manufacturers have not, as yet, furnished a reliable and rugged overhead switching device to change the path of the shoe from the main line to a branch line or a turnout, but are working on this problem with great hopes.

Plans are now being made for a regular inspection of the overhead distribution system and this inspection should keep the overhead in good operating condition. Linemen who had worked on the single-trolley system had much to learn about protecting themselves and their equipment when working on 2 conductors of opposite polarity only 24 inches apart.

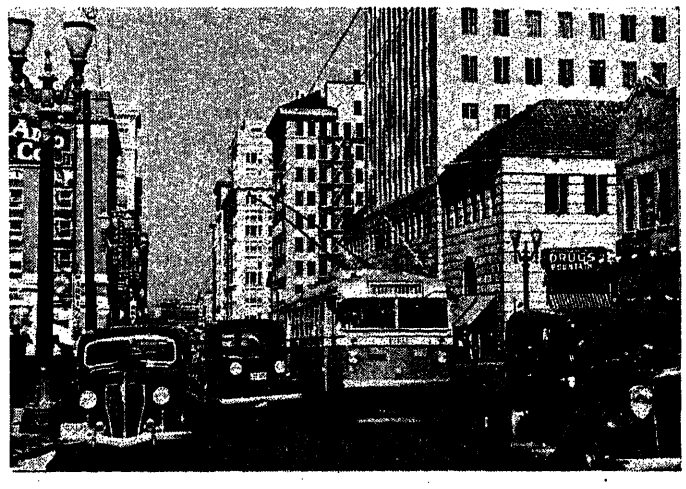
In considering operating costs, it must be remembered that this system has been and, in many particulars, still is in process of development. For example, several thousand dollars was spent in training operators, mechanics, and other employes, practically none of whom had had previous experience with trolley coaches and these development costs are included in the operating costs to date. With this qualification, some operating and statistical data are offered, all applying to the 12-month period immediately following operation of the first line.

## Operating Expenses per Coach Mile

| | |
|---|---|
| Power | 3.23 cents |
| Conducting transportation expenses | 8.80 cents |
| Traffic expenses | 0.18 cents |
| General and miscellaneous expenses | 2.48 cents |
| Total operation | 14.69 cents |
| Maintenance of way and structures | 1.02 cents |
| Maintenance of equipment | 3.01 cents |
| Total operation and maintenance | 18.72 cents |
| Provision for depreciation | 4.47 cents |
| General taxes | 0.94 cents |
| Bridge rentals | 0.14 cents |
| Total operating expenses | 24.27 cents |
| Operating ratio | 93.70 per cent |
| Proportion of total operating expense assignable to pay-roll expense | 46.0 per cent |

These expenses are based upon the following statistics:

| | |
|---|---|
| Total coach miles | 3,288,647 |
| Total coach hours | 260,638 |
| Total passengers carried | 15,041,743 |
| Total passengers per coach mile | 4.57 |
| Kilowatt-hours used per coach mile | 4.04 |



In the 34 cities in the United States where electric coaches are in operation, the coaches ordinarily seat 40 passengers and have both single-motor and 2-motor propulsion with the present trend toward the single-motor equipment. The single motor uses more power than does the dual motor but the saving in weight and cost in favor of the single motor compensates for the greater power consumption. The average speed of electric coaches in Portland is in excess of that in cities of similar size, or larger, and in some cases is 18 per cent greater.

The installation of electric coaches is the largest ever made at any one time in the United States, both in number of coaches and in the miles of route. The entire trolley coach system, consisting of 140 coaches and 45.5 miles of route, was put in operation within 9 months.

In general, the installation of electric coaches in Portland has left no regrets. Minor problems have been met and most of them have been solved. Manufacturers have been called upon to replace parts and have done so at their own expense. Voltage regulators on the first coaches received were replaced. The mounting of the 12-volt generator was improved. Brake lining did not give the expected mileage and was replaced with a different type. The recommended clearance between brake blocks and brake drums was increased and brake block mileage was very greatly increased and scoring of brake drums eliminated. Considerable change was made in the motor control by one manufacturer and additional change is still desirable.

The tire manufacturer has altered the tread in the hope of obtaining greater mileage. While operators were being trained and were gaining experience, tires suffered, particularly on account of rear wheels striking curbs while rounding curves, but, with the "breaking-in" period concluded, this sort of unusual wear has been almost entirely checked, with a resulting decrease in sidewall and tread damage.

The springs in the trolley base are light for the duty they are called upon to perform and in the near future it will be necessary to replace these springs. The springs are probably being permanently deformed and the tension slowly decreases until there is but little room left for adjustment. Some trouble has been experienced with defective castings but the manufacturer has replaced these castings in the overhead system with a new design and

better workmanship. Coils in the electric frogs have failed for no apparent reason and we have hopes of a new design for the overhead switching.

With the first schedule on a line changed from street cars to electric coaches the speed was slow until the operators had experience in operating coaches. Men experienced in operating motor vehicles made better operators than those without driving experience. The operation of street cars helped in combating traffic problems but experience in steering a vehicle seemed to be very necessary.

Street cars carry 5.51 passengers per car mile, electric coaches 4.79 passengers per coach mile, and motor

coaches 2.86 passengers per coach mile. The street car lines with heaviest travel were not changed to coach lines and these lines still carry the heaviest loads. The condition of track and possibilities of rerouting determined the lines where street car service was replaced by coaches. Density of traffic determined whether electric coaches or motor coaches would be operated on the line under consideration. In the future, track will be repaired but when the time comes for replacing rail, the track will be covered with pavement and the cars replaced with coaches. Some of the remaining street car lines are in territory with sparse population and these lines will be replaced with motor coaches.

In conclusion, it may be said that public reaction to the operation of trolley coaches has been good. Revenues have increased from lines replacing street railways, but it is too early to determine the amount of traffic drawn from paralleling street railway lines and it is known that there has been a certain amount of such diversion, notwithstanding that the lines have been several blocks apart. Experience to date indicates that the overhead system is operating satisfactorily. The type of conductor is being tested for wear, and tests are also under way to determine the best lubricant and method of lubrication. In this connection, it may be added that automatic lubrication from passenger vehicles is being tried. Wear records for trolley shoes are maintained and tests of other details concerning the coaches, such as lubricants and lubrication, brake linings and drums, and brushes on motors and generators, are under way. Tire treads of various kinds are also being tested. With another year of experience to draw upon, some more definite facts and figures will be available.

Collaborating in the preparation of the above data were Mr. W. H. Lines, vice-president and general manager of Portland Traction Company, Mr. Gordon G. Steele, general superintendent, Mr. James P. Tretton, superintendent of equipment, and Mr. E. W. Moreland, statistician.

## Engineering Curricula

IN AN ARTICLE entitled "What Should the Technical School Teach?" appearing in *Civil Engineering* for November 1937, pages 733–4, Scott B. Lilly, professor of civil engineering at Swarthmore College, asserted that "the great fear of the present executive is obsolescence—that some new process will develop which will make his whole plant valueless." Because of this fear many of the progressive companies are becoming ever more interested in the field of research. "Large companies maintain their own laboratories, while the small ones combine to form trade associations, hiring the best men they can find, and spending lavishly to discover new methods that will bring them added business."

Professor Lilly maintains that research has produced better materials, better manufacturing methods, and better design; moreover, it has affected the requirements for a four-year undergraduate course because of its demand for broader training. "The theory underlying a broad undergraduate training is that instead of trying to keep up with all the changes that are taking place in each field, a college should reduce the number of courses taught, do away with special curricula, and concentrate on the things it can do best. The time is still far distant when engineering will be all science. Many of the structures being built even today are standing not because the theory of design is absolutely correct, but because the computations result in a structure similar to one that has proved satisfactory. In some cases it may be years before theory catches up with practice. Nevertheless . . . colleges should teach the science of engineering—that is, . . . students should spend the major part of their four years on the underlying principles of engineering, devoting only a moderate amount of time to applications."

The author believes that teaching has been too much concerned with the formal processes involved. "Men have learned *how* to do things, rather than *why*. They learned rules. But would it not be better to teach all courses from the standpoint of developing principles? For years the student has asked why he must spend so much time on mathematics when practicing engineers have told him that they rarely, if ever, have occasion to use the calculus. He does not realize that he will use the type of reasoning he learned in the calculus, although unconscious of where he learned it. Mathematics, then, must be taught so that the principles remain, even though the formal processes, the rules, are forgotten."

A suggested new curriculum, designed to meet the demands of modern industry, would be identical for civil, mechanical, and electrical engineers for the first three years. "The courses would include mathematics, physics and chemistry, descriptive geometry, kinematics, mechanics (both analytic mechanics and strength of materials), electrodynamics, hydraulics, and thermodynamics. This work would occupy three-quarters of the student's time for the first three years. In the senior year, he would be allowed to specialize in that branch of engineering in which he is most interested. He would have had the basic courses in all three fields and could take any advanced course offered. Some attempt should be made in at least one of these selected courses to carry the man as far as he is able to go—to acquaint him with the frontiers of knowledge in that field, so that he can see that engineering is not a dead thing, but a living, growing profession that will demand his best efforts."

"The broad engineering education . . . must include courses that cover the human side as well as the material side of the profession. But a 'course' in college is not an end; if it fails to develop a keen desire to know more, to go into the subject more deeply, it may be worse than useless . . . The greater part of this kind of education must come after graduation — and this will be true no matter how many courses were taken in college. The most important thing, therefore, is to instill the desire to be well read and well informed, not as a window dressing, but as equipment to face social problems and do something about them."

# Stray-Load Losses of D-C Machines

By E. W. SCHILLING
MEMBER AIEE

R. W. KOOPMAN
ASSOCIATE AIEE

## Synopsis

This article describes a method of measuring stray-load losses which is readily adaptable to the test departments of the manufacturers. Usually no additional test apparatus will be required beyond that already available. The same arrangement used for a pump-back heat-run test is used with only slight modification. Experimental data are given showing the effect of speed, load, and field strength upon these losses.

STRAY-LOAD losses may be defined as the losses at any particular load which are not accounted for by the conventional methods of measuring and calculating losses. They are divided into 3 classifications according to the causes producing them, as follows[1]:

1. Loss due to eddy currents in the armature conductors.
2. Short-circuit loss of commutation.
3. Increased core loss caused by distortion of the main field by armature reaction.

Various methods have been proposed for taking these losses into account. It has been suggested that the no-load core losses plus armature $I^2R$ losses be multiplied by a constant whose value should be somewhere between 1.1 and 1.5.[2,3] Such a procedure is open to the criticism that it would require a great number of constants to take into account differences in design.[2]

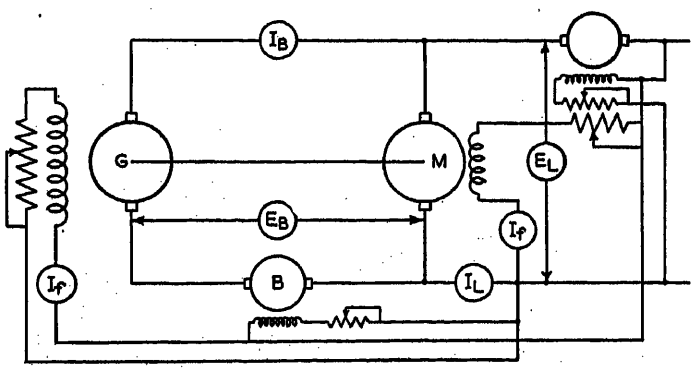


**Figure 1. Circuit used in determining stray-load loss of the set. Rotational losses supplied electrically**

Input-output tests have been made and data published.[2,4] The results of these tests were contradictory. One paper indicated high accuracy to be possible, whereas the other indicated that the method is not dependable.

Some work has been done on this problem[5] by using a generator with a compensating winding in the pole faces and comparing no-load losses with this winding unexcited to those when it is separately excited to various percentages of normal value. Of course, the first objection to this method is that most d-c machines do not have compensating windings. A further objection is that the additional loss determined in this manner is the result of field distortion and does not include losses in the armature conductors themselves due to eddy currents.

There is at present no standard way of directly measuring these losses, and according to the American Standards for Rotating Machines they are to be taken as one per cent of the output. This rule obviously makes no provision for differences in design and, in the case of adjustable-speed motors, charges the same loss to the machine at weak field and high speed as at strong field and low speed. That the latter is objectionable is clearly shown by the data given in this paper.

As a means of measuring stray-load losses, a direct measurement of total losses of 2 machines connected together in a modification of the familiar pump-back connection as shown in figure 1 is proposed. By subtracting the determinable losses from the total measured losses the total stray-load loss of the two is determined.

One of the contributions made by this paper is a method of allocating the proper proportion of the total stray loss to each machine when using the method described above; the other is informational in nature, that is, data are given on the stray loss resulting from operating d-c motors under varying conditions of speed, load, and field strength.

## Test Procedure

The circuit used for making the tests is shown in figure 1. *M* and *G* are machines of the same size, type, and design, and the brushes of both are set on neutral. They are therefore considered identical. Throughout any given test the field currents of the 2 machines were kept constant. The armature currents were varied by changing the booster (*B*) voltage.

The combined losses of the 2 machines *M* and *G* are

$$E_L I_L + E_B I_B = L_t$$

$L_t$ includes the armature $I^2R$ loss, commutating-pole-winding $I^2R$ loss, no-load core loss, brush-contact loss, windage and friction loss, and stray-load loss.

A paper recommended for publication by the AIEE committee on electrical machinery. Manuscript submitted April 22, 1937; released for publication October 8, 1937.

E. W. SCHILLING is associate professor of electrical engineering at Michigan College of Mining and Technology, Houghton, and R. W. KOOPMAN is assistant professor of electrical engineering at the University of Kansas, Lawrence. The authors are indebted to Mr. Scott Hancock, manager of the industrial motor engineering department of the Westinghouse Electric & Manufacturing Company, and to Professor G. W. Swenson, head of the department of electrical engineering of the Michigan College of Mining and Technology, for suggestions and information relative to this work.

1. For all numbered references, see list at end of paper.

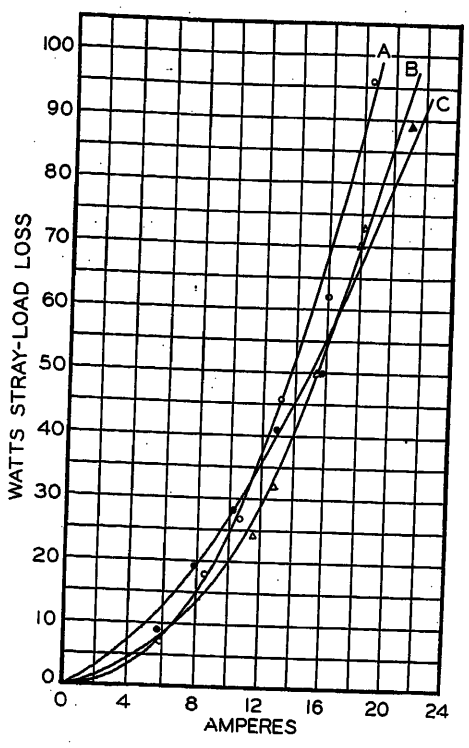

**Figure 2. Stray-load loss of set at 850 rpm, using circuit of figure 1, versus average armature current of the 2 machines**

*A*—Field current 0.50 ampere

*B*—Field current 0.66 ampere

*C*—Field current 0.80 ampere

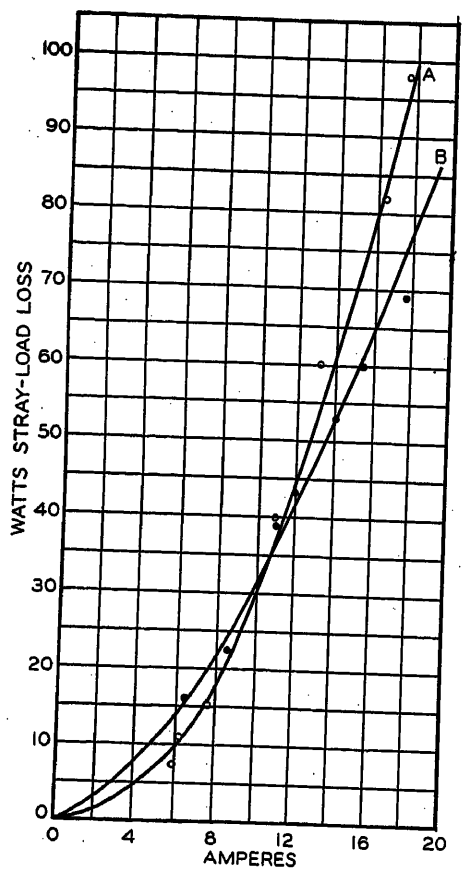

**Figure 3. Stray-load loss of set at 1,000 rpm using circuit of figure 1**

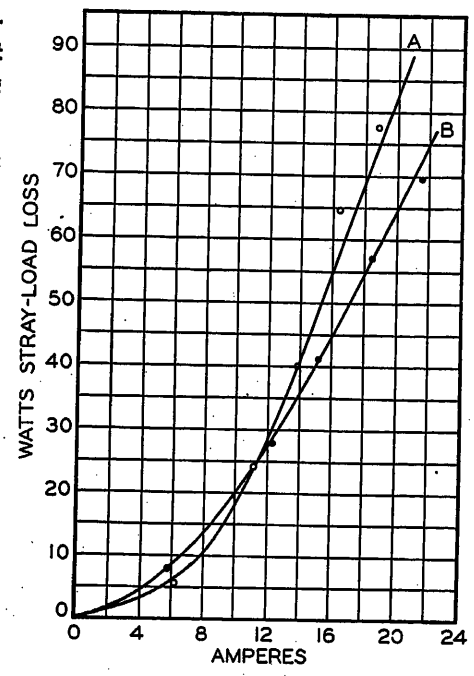
*A*—Field current 0.50 ampere

*B*—Field current 0.80 ampere



In order to insure that the various friction losses, the $I^2R$ losses, and, to a limited extent, the core loss would remain constant during the period required for taking the readings, it was necessary to run the machines until constant temperatures were reached. After this temperature was reached the brush contact drop was measured. Next the electrical input readings of $E_L$, $I_L$, $E_B$, and $I_B$ were taken. Immediately the line was opened, disconnecting the machine on the right; under this condition, the coupled machines come to rest, but the booster continues to circulate current of very nearly the same value as when all machines were in motion.

This convenience was of great value because the drops across the commutators and series resistances could be measured with very little loss of time and, consequently, with very little change in resistance between the time the input readings were taken and the time the resistance measurements were taken. As soon as the resistance measurements were completed the set was started again and run at the same value of armature current as before, in order that the temperatures would remain constant. The internal voltages of motor and generator were then computed. The field current of the motor was then changed to

**Figure 4. Stray-load loss of set at 780 rpm, using circuit of figure 1**

*A*—Field current 0.50 ampere

*B*—Field current 0.80 ampere

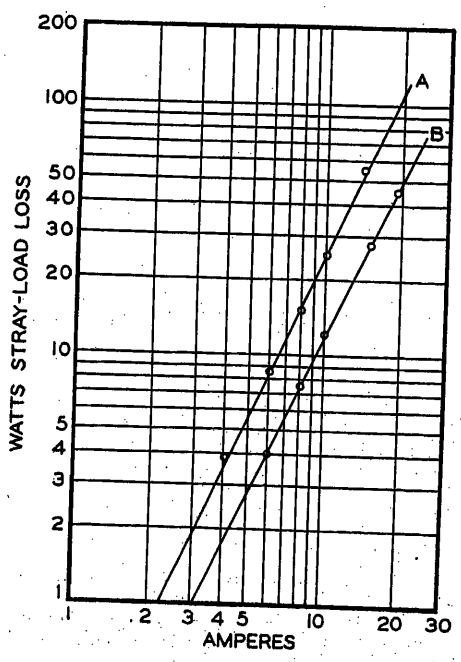


**Figure 5. Determination of exponent n at 850 rpm, 0.50-ampere field**

*A*—Loss versus average armature current of the 2 machines of set using circuit of figure 1

*B*—Loss versus armature current of one machine; losses separated according to scheme proposed

correspond to this voltage as read from the saturation curve, the booster circuit was opened, and the generator field current was adjusted to give the calculated internal voltage. The friction, windage, and core loss of the set could then be determined from the input to $M$ and its calculated $I^2R$ and brush-contact losses.

By taking the core-and-friction-loss readings immediately after each test, errors that result from wearing of brushes and from changes in bearing friction due to temperature changes were eliminated.

The stray-load loss of the set $L_s$ was taken to be $L_t$ minus brush contact loss minus $I^2R$ loss minus friction, windage, and core loss. A series of load-loss readings was thus taken at constant field current and speed for several values of $I_g$. These losses were then plotted against the average current of the 2 machines. Several different series of readings were taken using different speeds or field currents; these results are shown in figures 2, 3, and 4.

## Determination of Portion of $L_s$ Due to Each Machine

The curves mentioned above show how the total load loss of the set varies with average armature current, but do not give that due to each machine, because the armature currents are different.

We shall now describe the method used to separate $L_s$ into the components due to each machine.

Since we assume that the 2 machines are identical, and since they operate at equal field currents, the only variable affecting $L_s$ is the armature current. If the law of variation of $L_s$ with armature current were known it would be mathematically possible to calculate the portion of $L_s$ to be charged to each machine. Plotting $L_s$ versus average armature current gives us some idea of this law.

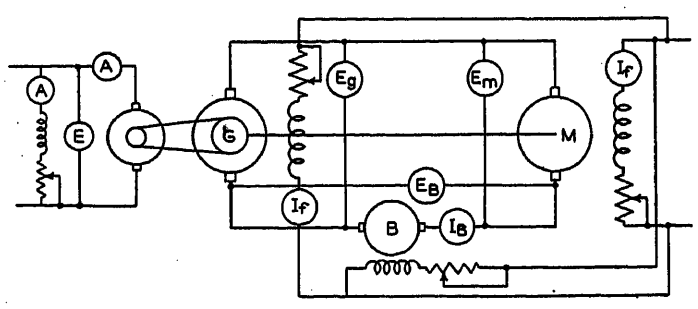

**Figure 6. Circuit for obtaining stray-load loss with same armature current in both machines**

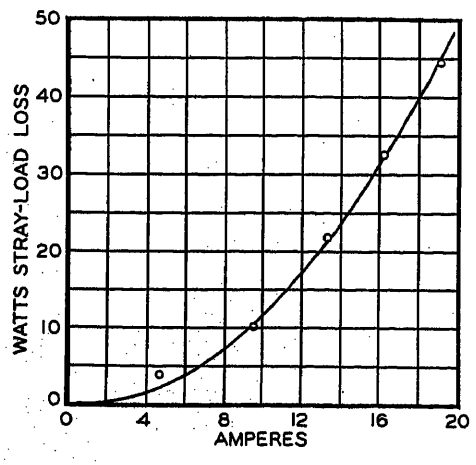

**Figure 7. Stray-load loss of one machine at 850 rpm, 0.50-ampere field, versus armature current. Curve calculated from test data obtained using circuit of figure 1. Circles represent test points obtained by using circuit of figure 6**

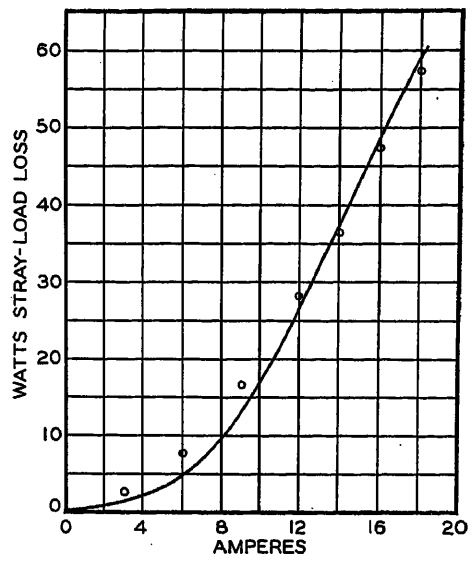

**Figure 8. Same as figure 7 but for 1,000 rpm, 0.50-ampere field**

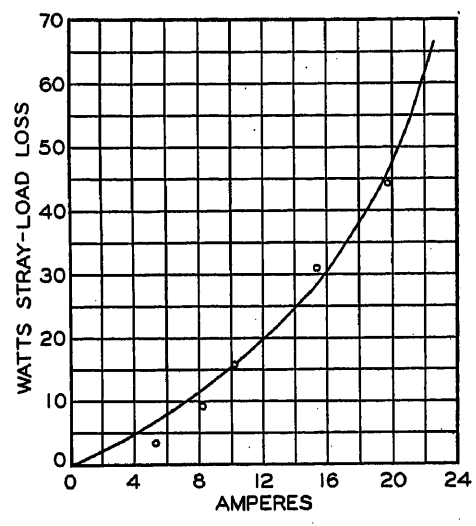

**Figure 9. Same as figure 7, but for 1,000 rpm, 0.80-ampere field**

Assuming that these curves can be expressed by $L_s = kI_a^n$ we can easily find $n$ by plotting on logarithmic paper as shown in figure 5*A*. Then at a particular value of $L_s$,

$$L_s = kI_G^n + kI_M^n$$

and the portions of $L_s$ chargeable to generator and motor respectively are

$$L_s \frac{I_G^n}{I_M^n + I_G^n} \quad \text{and} \quad L_s \frac{I_M^n}{I_M^n + I_G^n}$$

to the degree of approximation that $n$ approximates the true value of $n$ as it would be obtained by plotting the actual load loss of only one machine against its armature current.

Theoretically we could plot a curve of the load loss of one machine as obtained by using the approximate value of $n$ and obtain a new value of $n$, make a new separation, plot another curve, etc., until we approach the true value of $n$ as closely as we please. Practically, however, it is

necessary to make only one separation. That is shown in figure 5, where curve $A$ is the plot of $L_s$ versus average armature current and $B$ is the curve of the load loss of one machine plotted versus its armature current. There is scarcely any difference in the slopes of the 2 curves. The closeness with which the points fit the straight lines indicates that the equation $L_s = kI_a^n$ is correct to a high degree of accuracy.

In order to illustrate the method more clearly an example of a typical set of readings at 850 rpm and 0.5 amperes field is given.

$E_L$ = 94.80 volts
$I_L$ = 4.42 amperes
$E_B$ = 18.70 volts
$I_B$ = 11.05 amperes

| | |
|---|---|
| Generator brush contact drop (positive + negative) | = 1.40 volts |
| Motor brush contact drop (positive + negative) | = 1.80 volts |
| Generator armature current, $I_G$ | = 11.05 amperes |
| Motor armature current $I_M$ | = 15.47 amperes |
| Resistance of generator windings at operating temperature plus series resistance of 0.017 ohm | = 0.807 ohm |
| Resistance of motor windings at operating temperature plus series resistance of 0.012 ohm | = 0.847 ohm |
| *A.* Line supply watts | = 419 watts |
| *B.* Booster supply watts | = 206.6 watts |
| *C.* Total supply watts | = 625.6 watts |
| *D.* $I^2R$ generator | = 98.8 watts |
| *E.* $I^2R$ motor | = 203.0 watts |
| *F.* Brush-contact loss, generator | = 15.5 watts |
| *G.* Brush-contact loss, motor | = 27.9 watts |
| *H.* Core loss, friction, and windage of set | = 234.0 watts |
| *I.* Total of directly measurable losses ($D + E + F + G + H$) | = 579.2 watts |
| *J.* Stray-load loss $L_s$ = C − $I$ | = 46.4 watts |

## Determination of $L_s$ Chargeable to Each Machine

From figure 5*A*, $n$ = 2.16. Therefore the portion of $L_s$ chargeable to the generator is

$$46.4\ \frac{\overline{11.05}^{2.16}}{\overline{11.05}^{2.16} + \overline{15.47}^{2.16}} = 46.4\,\frac{179.35}{550.35} = 15.1 \text{ watts}$$

and that chargeable to the motor is 46.4 − 15.1 = 31.3 watts.

## Check on Procedure

As a check on the validity of the method which was used to separate losses, another series of tests was run on the set under the same conditions of speed and field current as before; but in this series the circuit of figure 6, in which the armature currents of the two were exactly the same, was used. In this test as in the other the same precautions regarding heating were observed. It was again possible to use the booster to circulate current for measuring $IR$ drops and thus save time, as no extra connections had to be made. The driving motor at the left in figure 6 was supplied from a variable-voltage generator. This voltage was reduced to a low value, and the field circuit

*A*—1,000 rpm; 0.50 ampere field current
*B*—850 rpm; 0.50 ampere field current
*C*—1,000 rpm; 0.80 ampere field current
*D*—780 rpm; 0.50 ampere field current
*E*—850 rpm; 0.80 ampere field current
*F*—850 rpm; 0.66 ampere field current
*G*—780 rpm; 0.80 ampere field current

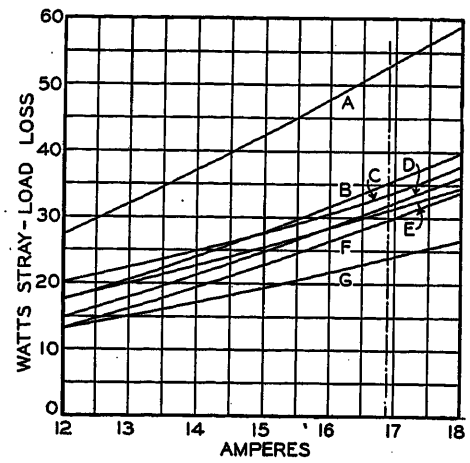

**Figure 10. Comparison of stray-load loss under different conditions of speed and field current**

of the motor opened. This stopped the set but still circulated current through the armature of the driving motor and thus simplified the measurement of resistance in this machine. The stray-load loss of the set is then equal to the booster output minus calculated losses of the set plus increased output of the driving motor between no current in the set and that current at which the test was run. Brush-contact drops were measured on all machines and these values used in calculating the brush-contact losses.

The stray-load loss under these conditions of operation should be the same for each machine. Figures 7, 8, and 9 were plotted from data obtained by applying the method of separation described in this paper to the curves of figures 2*A*, 3*A*, and 4*B*. The circles are test points obtained by using the circuit of figure 6. Here then are the results of obtaining the stray-load loss of a machine from 2 entirely independent and different tests. The results check as closely as could ever be expected in a test of this kind.

## Conclusions

In these tests a machine operating under different conditions of speed and field current shows a wide variation in load loss, as shown in figure 10. The broken vertical line indicates rated full-load current. The outputs of the machine are approximately the same at 1,000 rpm, 0.5 amperes field; 850 rpm, 0.66 ampere field; and 780 rpm, 0.80 ampere field, but the stray-load losses vary widely between these limits. This shows the need of a new rule for calculating stray-load loss for adjustable speed machines, as the present rule would charge the same loss at all three speeds. Another illustration of the inadequacy of the present rule is shown by figure 10. For instance, *B* and *C* intersect at about 14.8 amperes. The data given in this paper show that the load losses are equal at these intersections; yet the outputs are different in that they correspond to a speed of 850 rpm and field of 0.5 amperes for *B* and a speed of 1,000 rpm and field of 0.8 amperes for *C*. The present rule would charge different load losses for the 2 conditions.

All the curves taken with weak field show steeper slopes in the region of high armature current than those taken with the stronger field. The reason for this difference is that the armature current has a greater distorting effect on the resultant field when the main field is weak.

The advantage of using this method over the input-output test is that losses are measured directly, whereas in the input-output test they are taken as the difference between two relatively large quantities. The improvement in accuracy is obvious.

Another advantage is that very little wiring is required beyond that for the pump-back heat-run test as it is set up by many manufacturing companies. No special equipment is needed, and the labor required is comparatively low.

Its disadvantage is that the machines must be assumed to be identical.

The losses obtained were higher than expected, probably because the air gap was shorter than the average. This in itself is another fact which indicates the necessity of adopting a test procedure for determining stray-load loss.

# The Library as an Engineering Tool

LITTLE excuse exists for those engineers who fail to furnish the correct answer to a current problem if it can be deduced, at least in part, from information available in libraries, according to an article by Gregory M. Dexter appearing in the November 1937 issue of *Mechanical Engineering*, pages 845–9. The author believes a library to be an engineering tool worthy of more than passing thought, because "some [engineers] find it easy to go along in the daily job without sensing or taking time to study the implications of new developments in unrelated or even in related fields of their daily activity. When suggestions are made for improved methods, many of them at some time say, 'it cannot be done.' They have not had sufficient interest or leisure to find out whether conditions have changed, new developments have occurred, or the previous failure did not arise from some fault in management or application of method."

Many engineering problems are settled easily by reference to the latest books; consequently, one of the most valuable source books for the engineer is the catalog of the large publisher of technical books. Yet often he will find that the best book on a particular subject is not published by one of the large technical publishing houses, and if he is thorough in his search for knowledge, he may find that the book he wants can be obtained only from some publisher of whom he has never heard.

"Many problems which engineers have to solve are so involved in technicalities, so unusual, or so special in application that no book available gives more than an elementary discussion. Places to which an engineer may turn then are the various departments of the federal and state governments as well as the numerous experiment stations.

"He should have always available a complete set of the indexes of federal publications which are obtainable from the Superintendent of Documents, Washington, D. C. . . . If the particular subject in which he is interested is not listed, a letter to the appropriate federal department often will bring him valuable information on unpublished data or other suggestions."

The author admonishes the reader that the titles to some of the general indexes are likely to deceive the engineer concerning their actual scope, and that valuable information sometimes may be obtained from the most unlikely appearing sources.

"Services of a librarian often are used in making searches for engineers. No disparagement of the value of such services is intended . . . . but engineers should recognize how much better results could be obtained by an engineer instead of a librarian. The engineer appreciates all ramifications of the problem he is investigating. He needs, of course, the facility a librarian has in knowing how to use a library. He needs persistence and imagination. Yet an engineer who knows his subject and has those qualities plus some knowledge of the library undoubtedly could do a better job of searching than a librarian. Merely glancing over an article would tell him whether it was worth abstracting or only listing in his bibliography.

"No engineer should entertain the idea that a library search is a method of avoiding original thinking. It is only a method of avoiding unnecessary expense in repeating mistakes that other men have made. It is a way of trying to start with new designs, inventions, or developments where other engineers and inventors have stopped."

The article contains comprehensive listings of book catalogs and indexes, government publications, guides and indexes to economic data, and general and special indexes. Most libraries have special bibliographic facilities of their own which should not be overlooked, and the author suggests ways of obtaining and using these special facilities.

# Oil Oxidation in Impregnated Paper

By J. B. WHITEHEAD
FELLOW AIEE

T. B. JONES
ENROLLED STUDENT

## Introduction

MUCH HAS BEEN written recently on the influence of oil oxidation on the properties and stability of impregnated paper insulation. It is thought by many to be a principal cause of deterioration in high voltage cables. Oxygen is highly soluble in cable oils; if present in appreciable quantity and at moderate temperature elevation, the oils oxidize rapidly with consequent loss of insulating value. However, the amount of oxygen remaining in a carefully dried paper cable is so small, and the oxidation process is so slow that it remains to be proved that it is more important in deterioration than other well-known causes.

In this paper we report a series of studies of the oxidation process in cable paper impregnated with oil containing different amounts of oxygen, as indicated by changes in well-known electrical quantities. Separate studies of the effect of equal amounts of air and of nitrogen, and of the behavior of the oil alone, and as affected by paper and metal, throw interesting light on the nature of the progressive changes found in the electrical characteristics.

## Experimental Method

One type of oil and one type of paper were used throughout. Ten layers of the paper were assembled in a small parallel-plate capacitor, equipped with the usual guards, and mounted in a Pyrex glass dish, and placed inside an evacuating and impregnating tank with temperature control. See figure 1. The paper is evacuated at 0.05 millimeter of mercury pressure to a standard degree of dryness and the oil admitted for impregnation. Before admission the oil is filtered, degassed, and saturated with oxygen at various pressures, and impregnation takes place in an atmosphere of oxygen at the same pressure. After impregnation the sample is kept at the same constant pressure and at a temperature of 80 degrees centigrade for about one week. Measurements of power factor and capacitance, as related to voltage and temperature (at end of test) were made at intervals. At the end of the run the power factor of the individual paper layers, and the electrical properties of the oil drained off the specimen, were measured. Additional studies were made on the oil alone and on the impregnated paper using nitrogen as impregnating atmosphere. The catalytic effect of several metals on oil oxidation was also measured.

A paper recommended for publication by the AIEE committee on research. Manuscript submitted September 16, 1937; released for publication October 15, 1937.

J. B. WHITEHEAD is professor of electrical engineering and dean of the faculty of engineering at The Johns Hopkins University, Baltimore; T. B. JONES, formerly a graduate student at The Johns Hopkins University, now is a member of the technical staff of Bell Telephone Laboratories, Incorporated, New York, N. Y.

*The Paper and the Oil.* A single grade of uncalendered chemical wood pulp "kraft" paper, as made by a well known manufacturer was used throughout. Its properties[1,20,21] are given in table I.

The oil, designated by the refiner as "highly refined paraffin" cable oil, was delivered protected by nitrogen atmosphere and so maintained until used. Its properties are given in table II.

*Test Capacitor.* The capacitor is of circular parallel-plate type; high-voltage electrode 13-centimeter diameter, low-voltage electrode 10.4-centimeter diameter, equipped with guard ring, radial width of gap and ring 1.25 centimeters; material, brass throughout.

Ten circular sheets of paper 15.6-centimeter diameter constituted the usual test sample. A constant weight was placed on the upper high-voltage electrode to ensure uniform pressure in all samples; air capacitance at this separation, 71 micromicrofarad . The capacitor is mounted in a shallow Pyrex glass dish, which is placed in a vacuum-tight, temperature-controlled impregnating tank shown in figure 1. The tank can be evacuated to 0.05 millimeter of mercury, and heated to 110 degrees centigrade. The oil is admitted through Pyrex tubing, and the removable top

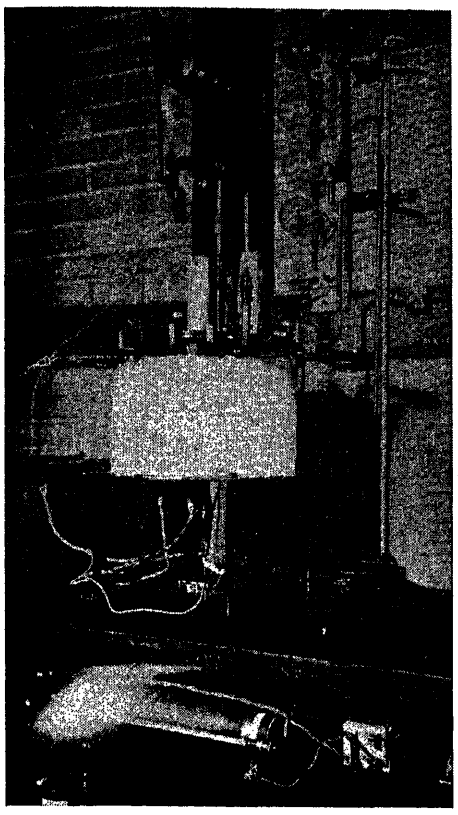

Figure 1. The test cell

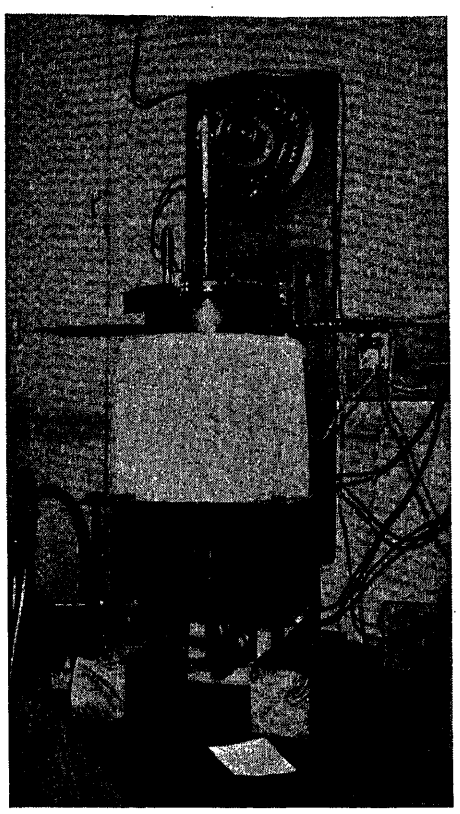

Figure 2. The oil filter cell

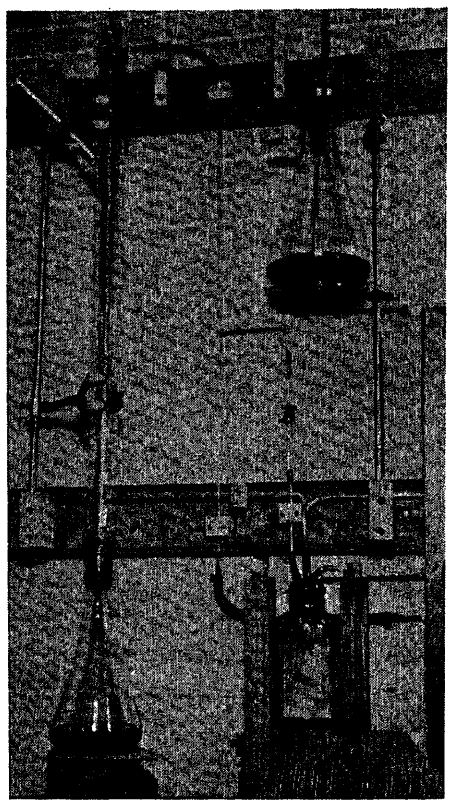

Figure 3. The degasification and dehydration apparatus

carries glass bushings for the electrical connections.

*Oil Purification and Oxidation.* The oil as received is first passed through the glass wool filter shown in figure 2, and then through the combined vacuum degasifier and dehydrater shown in figure 3. In the latter the oil passes down in a thin film over the turns of an open spiral of Nichrome wire in the inner of 2 coaxial glass tubes. The outer tube contains a heating coil; temperature in operation 80 degrees centigrade, pressure, 0.2 millimeter of mercury. After this treatment the oil had a power factor (60 cycles) of 0.0003 and a breakdown strength (standard disk gap) of 30,000 volts at room temperature.

*Oxygen Content of Oil.* Oxygen was admitted to the oil in different amounts, by exposing it to the gas at different pressures, in the apparatus shown in figure 4.

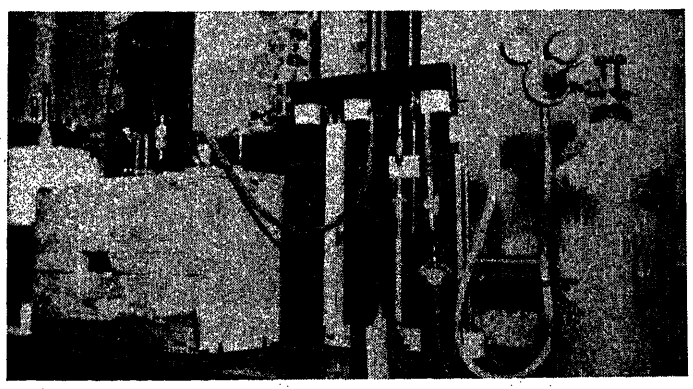

Figure 4. The oxidation apparatus

It has been shown that the volume absorbed-pressure relation is linear over a wide range,[22] for equal times and temperatures of exposure. In this work the oil was first raised to a temperature of 80 degrees centigrade, and evacuated to 0.1 millimeter of mercury. Then dry oxygen was admitted and the sample allowed to absorb oxygen for a period of 65 hours at constant pressure. The values of pressure adopted for study were 1 millimeter, 5 centimeters, 10 centimeters, and 76 centimeters of mercury. In what follows the different samples will be referred to in terms of these pressure values. The amount of oxygen absorbed in the several 1,000-cubic-centimeter samples at the respective pressures was found to be as given in table III. It will be seen that the relation between pressure and volume absorbed is approximately linear.

*Impregnation.* The test electrodes were washed in successive baths of soap and water, benzine, alcohol, or carbon tetrachloride, and distilled water, and dried. Ten layers of paper were placed between the plates and the whole placed in the impregnating and measuring tank. The temperature was raised to 105 degrees centigrade, and the pressure reduced to 0.1 millimeter of mercury. Frequent measurements of power factor and conductivity were taken in order to follow the drying process. Constant values indicating extreme state of dryness were usually reached in 72 hours; power factor, 0.00140; conductivity $1.0 \times 10^{-15}$ mhos per cubic centimeter. When these values were reached the temperature was lowered to 80 degrees centigrade and the oil, after treatment as already described, was admitted for impregnation.

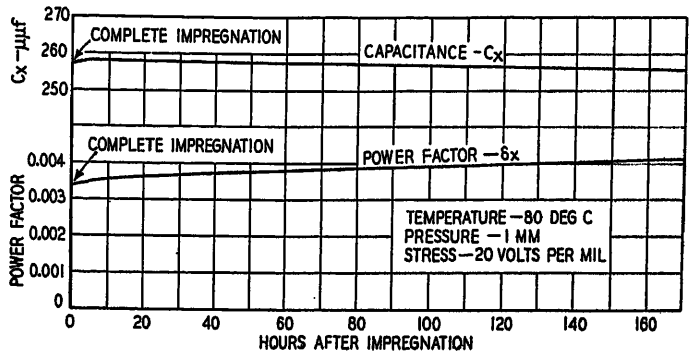

**Figure 5. Power factor and capacitance versus time**

In each case impregnation took place in an atmosphere of oxygen and at the same pressure and temperature at which the oil had been saturated. Thus for the 5-centimeter test the oil was preoxidized at 5 centimeters of mercury pressure and 80 degrees centigrade, and admitted to the dry paper at the same pressure and so maintained. The glass dish containing the capacitor was filled with oil and so remained throughout the test, so that there was a constant supply of oil and gas at constant pressure throughout the test. After admission of the oil the sample was allowed to stand for 24 hours to ensure complete impregnation. In the results reported below the end of this 24 hours is taken as *zero* time. Thus at this stage the oil had already been exposed to oxygen at 80 degrees centigrade during gas saturation, and paper impregnation, for a total of 89 hours. Electrical measurements were begun at this point, and consisted of power factor and capacitance at 60 cycles, and 20 volts per mil of paper thickness, 3 times a day; and a power factor-voltage run up to 150 volts per mil once each day. This program was followed for 168 hours, the duration of the normal test.

After the normal test, heat was removed from the tank (pressure constant) and during cooling the power factor-temperature curve of the sample taken for the range 80 degrees–25 degrees centigrade; a power factor-voltage curve was then taken at room temperature. The oil was drained from the sample for further test; the sample was then disassembled and consecutive measurements made of the power factor of each layer; the successive layers were carefully examined for any evidence of gas spaces, wax formation, or other significant condition.

At no time during the above tests was sustained voltage applied to the samples, and the electrical measurements 3 times a day were of brief duration and at low stresses. Thus the various behavior of the samples, as observed, is due to the oxidation process alone.

*Electrical Measurements.* Power factor and capacitance were measured on the transformer bridge developed in these laboratories by Seletzky[31] and McCurley.[24] It has a power factor accuracy of 0.0001 and can be balanced in less than 3 minutes. It lends itself readily to variations of setting needed for ranges of voltage stress, and for tests on single paper layers. The standard air capacitor is of flat type with electrodes 14 by 28 inches; the capacitance is 179 micromicrofarad. The output transformer feeds into a resistance-capacitance coupled amplifier. The detector is a vibration galvanometer; sensitivity, 40 millimeters deflection per microampere, at one meter distance of scale. A high sensitivity d'Arsonval galvanometer was used for d-c conductivity measurements, under methods described in earlier papers.[1]

## Experimental Results

Five series of observations were made of the influence of oil-absorbed oxygen on the behavior of impregnated paper. These will be referred to as the 1-millimeter, 5-centimeter, 10-centimeter, and 76-centimeter tests for pure oxygen. The fifth series covers a sample with oil treated at one millimeter *air* and impregnated and tested at one millimeter *air*, the process being identical in all other respects with the one-millimeter oxygen test.

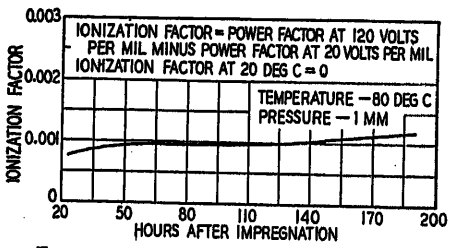

**Figure 6. Ionization factor-time**

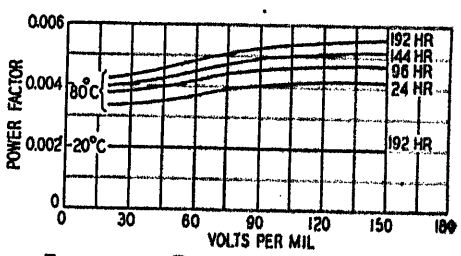

**Figure 7. Power factor-voltage**

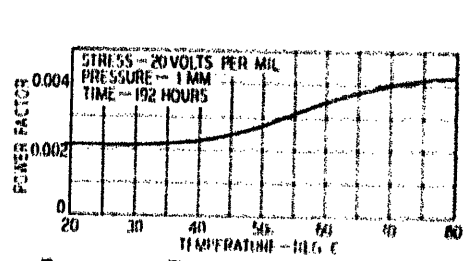

**Figure 8. Power factor-temperature**

*One-Millimeter Oxygen Test.* The results are shown in figures 5, 6, 7, 8, and 9. The capacitance, figure 5, is constant over the 168 hours of the test. The power factor rises very slightly from 0.0038 to 0.0042.

The power factor-voltage relations taken at 24-hour intervals are indicated in figure 7, and the resulting ionization factors in figure 6. The power factor-voltage curves at 80 degrees show a rising tendency at first, but evidently indicate an approach to a maximum value of

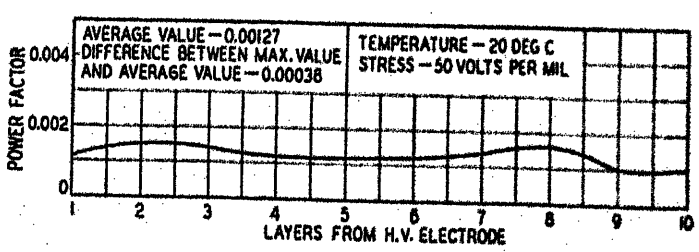

**Figure 9. Layer variation of power factor**

power factor. This behavior has been noted in earlier[1] studies of well-impregnated samples, although at lower stresses. The power factor at 20 degrees is constant between 20 and 150 volts per mil. These facts indicate the relative unimportance of gaseous ionization and suggest the presence of some type of oil ionization increasing with temperature and time, and voltage, up to a certain value. The increase with temperature, figure 8, is due to the increased mobility of the liquid ions; the increase with time to the increase of the number of ions with progressive oxidation or other cause; the increase with voltage is due to either increased mobilities, or new ions formed under increased stress, due to collision or other cause. The maximum of power factor results from a maximum conduction current when all ions are withdrawn as fast as formed. Other evidence in support of this view is given hereinafter. Other suggestions of mechanisms of the formation of new liquid ions are those of Inge and Walther[7] and Arman and Starr.[25]

Figure 9 shows the variation of power factor between successive paper layers. It is seen that the power factor is fairly uniform from layer to layer throughout and of a very low average value. The maximum variation is only 0.0006 power factor. The maximum of power factor occurs in the eighth layer from the high voltage electrode,

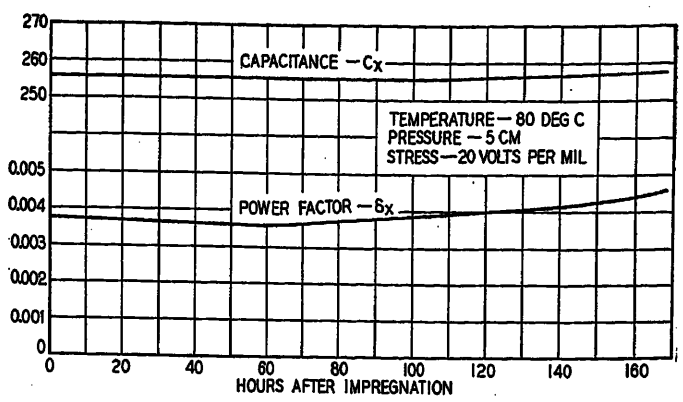

**Figure 10. Power factor and capacitance versus time**

creased rising tendency in the latter beyond 120 hours. This indicates that the 50-fold increase in oxygen content has a scarcely noticeable effect on these curves. The power factor-voltage curves, also, figure 12, except for some irregularity in the early stages, are substantially flat at 80 degrees up to about 100 hours, and do not rise above those of the one-millimeter sample until the end of the test, where the maximum value at 150 volts per mil is only 0.006. At 22 degrees the curve is definitely flat up to 150 volts per mil, at 0.0026 power factor; this is

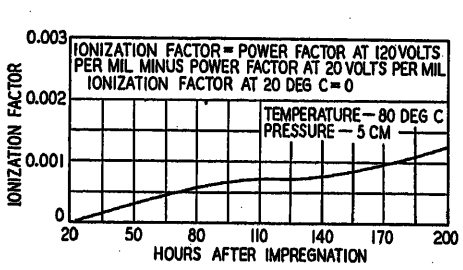

**Figure 11. Ionization factor-time**

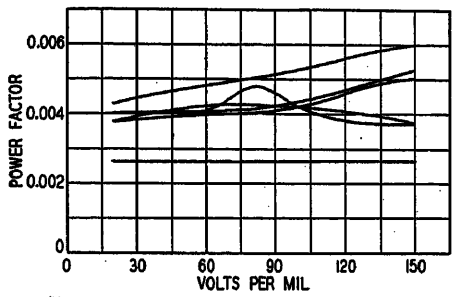

**Figure 12. Power factor-voltage**

**Figure 13. Power factor-temperature**

and not at the layers adjacent to electrodes as frequently observed. Indeed, at the electrodes the power factor is at its lowest values, indicating that at the low oxygen content here in question, the electrode-oil reaction does not appear within a period of 200 hours at 80 degrees centigrade. Apparently, therefore maxima of power factor in layers adjacent to conductor and sheath sometimes observed in new cables are due to some other cause.

*5-Centimeter Oxygen Test.* The results are shown in figures 10, 11, 12, 13, and 14. The capacitance-time, and power factor-time curves, figure 10, are closely the same as in the one-millimeter test, with a somewhat in-

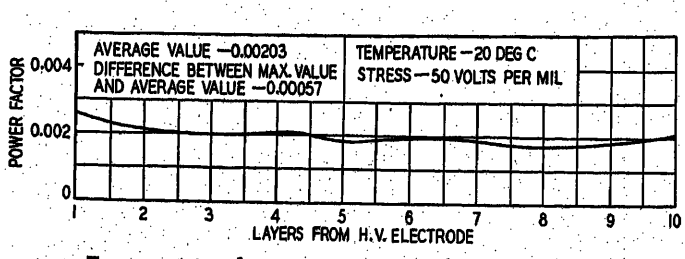

**Figure 14. Layer variation of power factor**

slightly higher than the corresponding curve, 0.002, at one millimeter, due probably to the increased oxidation. This, however, has little or no effect on the ionization characteristics, see figure 11. In fact up to 120 hours at 80 degrees centigrade, the electrical properties of this sample are substantially the same as those of the sample containing only one-fiftieth as much oxygen, and only slightly impaired beyond. The layer-power factor curve indicates the beginning of catalytic action of the brass electrodes.

These facts suggest that the deteriorating effects of small amounts of oxygen are either negligible or very long delayed in good cable insulation in normal service; also that a substantial amount of oxygen might be present in new cable, and not show itself for sometime.

*Tests at 10 Centimeters and 76 Centimeters of Mercury Pressure Oxygen Content.* In order to accelerate the oxidation process still further, similar tests at much greater values of oxygen content were made, that is, the oil was saturated with oxygen at 10 centimeters and 76 centimeters of mercury pressures, respectively. The results are shown in figures 15 to 19, respectively in which

the results at lower pressures are also included for convenient comparison.

Figure 15 shows the power factor plotted against oxygen content, as indicated by saturation pressure, for four different periods of time at 80 degrees centigrade after impregnation. Each curve thus represents an increased stage of deterioration, at any value of oxygen content. It is seen that for all curves the variation of power factor between one millimeter and 5 centimeters pressure is scarcely noticeable. Beyond 5 centimeters the increase with pressure is at first rapid, but then becomes slower again as the very high oxygen content of 76 centimeters is approached.

Figure 18 shows the power factor-temperature relation for each pressure. At low temperatures (20 degrees centigrade) the power factor is less than 0.004 for all values of oxygen content, and at 76 centimeters is only 1.8 times that at 1 millimeter. The differences are increasingly great, however, at higher temperatures. Thus the well-known influence of increased temperature in increasing the rate of oxidation is reflected in these power factor curves. In the 2 lower curves the practically linear increase may be explained as due to decreasing viscosity and increased ionic mobility. But the rapid rise in the 2 upper curves seems to require other explanation inherent in the oxidation process, such as the liberation of gas (hydrogen) and the consequent formation of water, and the formation of organic acids. Or more simply, we may note that the "velocity constant"[26] of the oxidation reaction increases exponentially with the temperature. If the reaction itself provides (even temporarily) an increase in the number of free ions, the observed increase in power factor is readily accounted for. Further evidence in support of this view is given later. No visual evidence of gas was found in the dismantling of any of the specimens. Figure 17 shows the temperature increase of power factor as function of the oxygen impregnating pressure.

Figure 16 shows the rapid increase beyond impregnating pressure 5 centimeters of ionization factor with value of oxygen content. The increase is very slight at one millimeter and at 5 centimeters, but very pronounced at higher impregnating pressure, as may be also seen in the power factor-voltage curves of figure 20 for 10 centimeters, and figure 21 for 76 centimeters. These increases of power factor with electric stress are not due to the liberation of gas, and to gaseous ionization; no free gas or other traces of ionization of this character were encountered. Rather the increase is to be attributed either to an increase in the number of ions due to some type of secondary ionization, or to an increase of ionic mobilities due to the stripping, under increased stress, of the outer envelopes of neutral molecules from the ions already present, or to both these causes. The flattening out of some of the power factor curves seems to support the latter view. Support of the former is found in the abrupt drop in power factor when the oxygen content and volatile products are withdrawn, as reported below; this indicates that during the oxidation process a large number of highly mobile ions are present.

Figure 19 affords a view of how the layer variation of power factor varies with oxygen content. As already stated a substantial amount of oxygen is needed to show itself in this way.

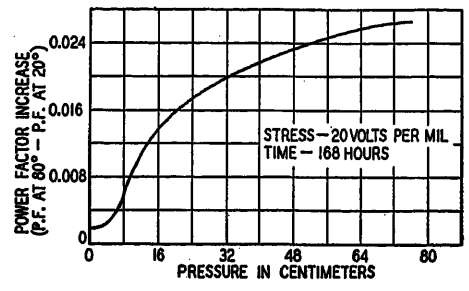

**Figure 17. Temperature increase of power factor**

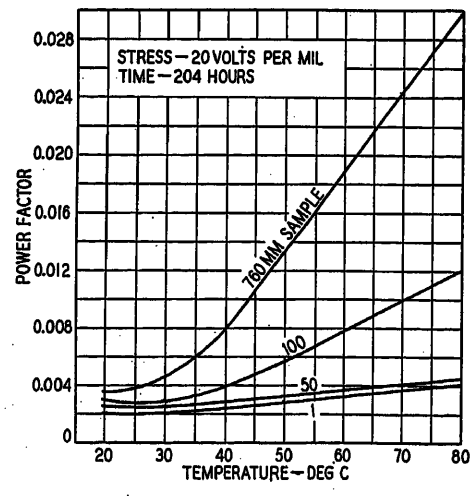

**Figure 18. Power factor - temperature**

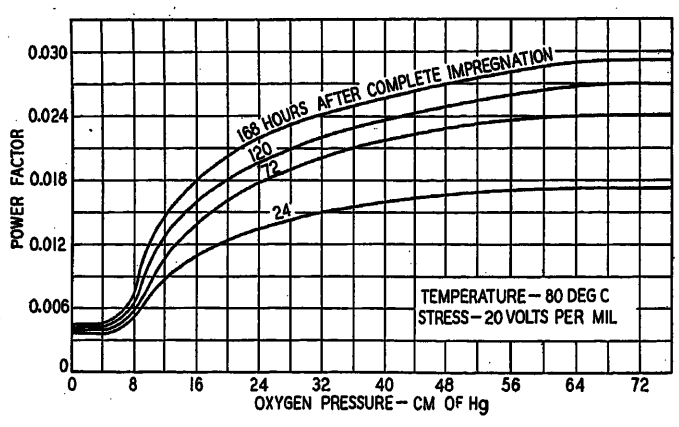

**Figure 15(above). Power factor-pressure**

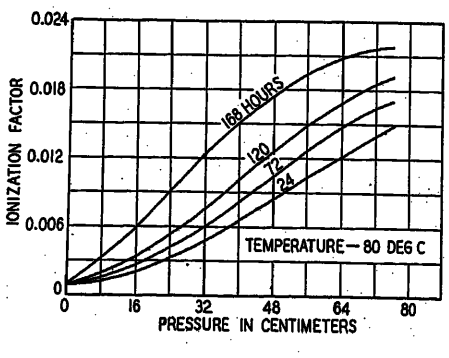

**Figure 16. Ionization factor-pressure at different times after impregnation**

It is interesting to note that the capacitance of all the impregnated samples over the whole range of oxygen content was the same, and remained constant over the duration of each test. This indicates that notwithstanding the heavy oxidation of the 10-centimeter and 76-centimeter samples, no appreciable molecular or ionic polarization was evident.

*Impregnation in Air at One Millimeter Pressure.* For comparison with the results using pure oxygen, a sample in which oil saturation and paper impregnation took place in *air* at one millimeter pressure, was tested, all technique being the same as for the sample impregnated at one millimeter of oxygen. The results are shown in figures 22, 23, and 24. Certain noticeable differences from the oxygen sample are evident. The capacitance, while constant over the duration of the test, has a substantially lower value, 243 versus 258 micromicroforad. The power factor-time curve for 20 volts per mil is about the same in the 2 cases. The power factor voltage curves

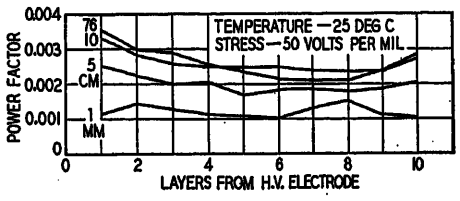

**Figure 19. Layer variation of power factor**

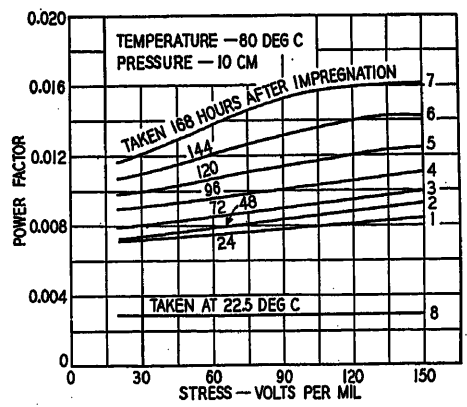

**Figure 20. Power factor-voltage**

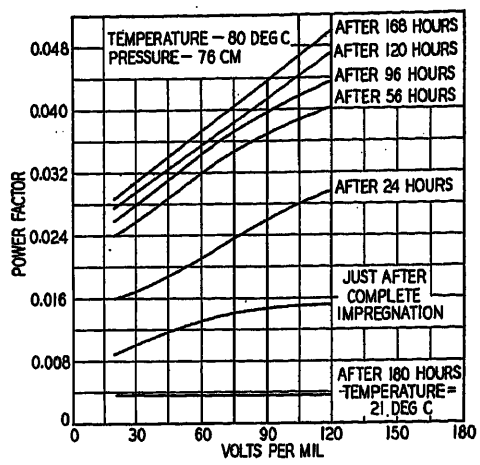
at 80 degrees centigrade for oxygen are of uniform shape and progressively higher with time. Those for air show some irregularity, but at first become lower, and finally only become higher with time. The constant values at 20 degrees to 25 degrees after the oxidation runs are substantially the same. The power factor by layers after oxidation shows only small variations, with little evidence of increase at the electrodes. All of these facts indicate superior impregnation for the oxygen sample, probably due to its greater solubility in the oil. Penetration into the pores of paper is not as complete for the air sample and thus the capacitance is lower. For the same reason the ionization factor, and power factor-voltage curves are higher at the start, then decrease with slow improvement of oil penetration, and then increase again as the slow increase of oil conductivity due to oxidation makes itself felt. On dismantling the air sample

**Figure 21. Power factor-voltage**



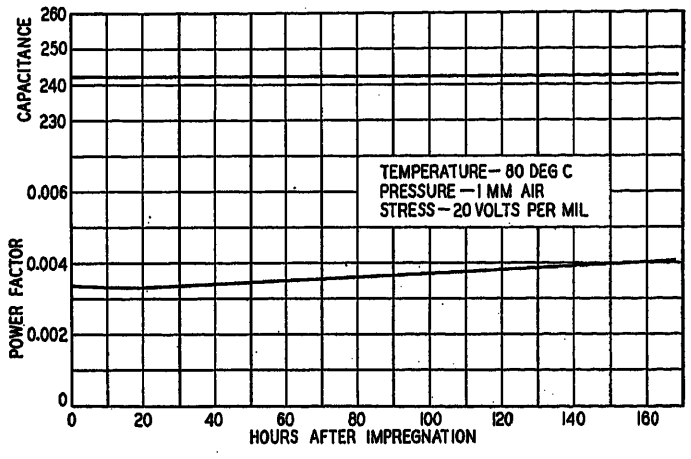


**Figure 22 (below). Power factor and capacitance versus time—air**

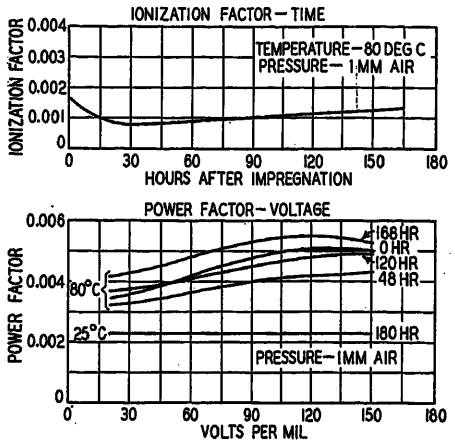
after the oxidation test, a few tiny bubbles of gas were evident in the paper layer next to the high voltage electrode, but in no other layers, and this may account for the slight rise in power factor for layer 1 seen in figure 24. In general it may be said that the sample impregnated in oxygen is superior to that impregnated in air, in the matter of impregnation, and shows no evidence of more rapid deterioration in the accelerated oxidation tests.

*Impregnation in Nitrogen at 10 Centimeters Pressure.* As a check to the deductions made from the results of the one-millimeter air test, a test was made using nitrogen at 10 centimeters of mercury pressure, for oil saturation and for impregnation. Figure 25 shows the variation of capacitance and of power factor over the duration of the test. On both curves the dotted lines give the measured values, and the full lines the trend of the average values. The values shown are for a stress of 20 volts per mil, and it was found that at this low and constant value neither capacitance nor power factor showed any tendency to change. However, power factor-voltage runs at intervals, up to 150 volts per mil, always resulted in a large increase followed by decrease to steady values at 20 volts per mil. The general sequence of these changes is indicated in the dotted lines of figure 25.

The decrease of the ionization factor, figure 26, and the continuous fall of the position of the power factor voltage curve with time, figure 27, are clear evidence of delayed impregnation. Power factor values at the end of the test

are generally of the same values as found in the one-millimeter oxygen test, showing the inert property of nitrogen and the very low oxidation activity at one millimeter oxygen content. The high position of the initial power factor-voltage curve is probably due to free nitrogen and gaseous ionization; small bubbles of gas were



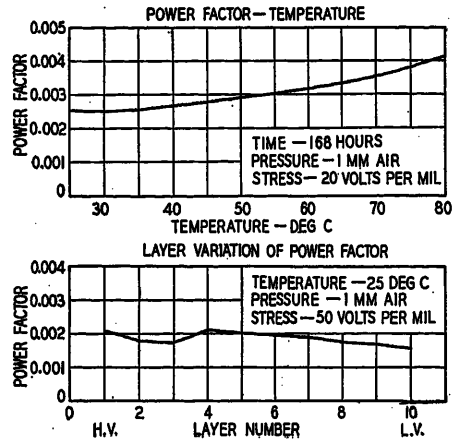


**Figure 23. Power factor-voltage and ionization factor-time**

found in the paper layers next to the electrodes but not elsewhere. Increasing the gaseous ionization by increase of voltage, seemed to stimulate the impregnation process, figure 25. The gas at the electrodes apparently also accounts for a slightly increased power factor (0.0032) of the paper layers next the electrodes, as compared with the approximately constant value (0.0028) of the interior layers.

It will be noted that the behavior of the one-millimeter air specimen presents several of the features of this specimen heavily saturated with nitrogen; for example, initial decrease in ionization factor, initial fall of position of successive power factor-voltage curves. There is a distinct indication that the nitrogen is playing its part in the one-millimeter air specimen.

*Properties of Oxidized Oil.* After each test the oil was drawn off the specimen and electrical measurements made on it. Thus there were available a series of oils oxidized for approximately 200 hours at 80 degrees centigrade in the presence of brass and paper, but at different constant amounts of contained free oxygen indicated by 0.013, 0.70, 1.40, and 10.4 per cent, respectively, of the constant volume of oil. The power factor-temperature curves of figure 28 and the power factor-voltage curves at 80 degrees, figure 29, show the relatively small difference in power factor over the range, pure oil—one millimeter—5 centimeter oxygen content, the rapid increase above 5 centimeters and the slower rate of rise toward 76 centimeters. The power factor-voltage curves of these deteriorated oils at 20 degrees centigrade were all found to be perfectly flat up to 60 volts per mil, but at 80 degrees centigrade all show the rising characteristics of figure 29, that is, some form of internal liquid ionization which increases with stress. The explanation is not obvious; possibilities in the order of their probability would appear to be increased ionic mobility, increase in free ions liberated during the

**Figure 24. Power factor - temperature and layer variation of power factor**

process of oxidation, and increased ionization by collision with increasing stress. The concurrent dominating influence of temperature is shown by the flat power factor-voltage curves at 20 degrees for all samples. The electrical characteristics of the deteriorated paper samples follow the same general trends as those of the oil withdrawn from them, indicating clearly the influence of the oil on the characteristics of impregnated paper.

*Influence of Brass and of Paper on Oil.* It has been assumed in the foregoing that the small increases in power factor found in the tests of the sample having one

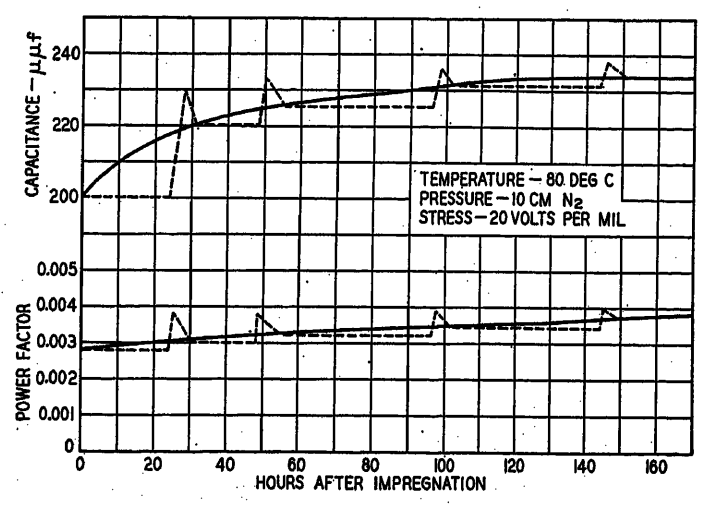

**Figure 25. Power factor and capacitance-time**

millimeter oxygen content were due to oil oxidation. However, during these tests the oil is in contact with both brass and paper and it remains to be seen whether or not these elements have any effect on the pure oxygen-free oil. In order to obtain a quantitative answer to this question, 3 identical pure samples of oil were prepared and heated for 48 hours at 80 degrees centigrade under the following conditions: (1) oil alone; vacuum 0.1 millimeter; (2) oil plus 800 square inches of paper; vacuum 0.1 millimeter; (3) oil plus 40 square inches of clean sheet brass; vacuum 0.1 millimeter. The heating took place in a Pyrex glass flask and before the oil was admitted paper and brass were given thorough degassing and dehy-

drating treatments at 105 degrees centigrade and 0.1 millimeter vacuum. At the end of each test the sample was cooled to room temperature, then placed in the test cell and a power factor-temperature run made. The results of the 3 tests are given in figure 30 (which also shows results of a similar test on the oil drawn from the 10-centimeter nitrogen sample after the deterioration test).

We note from figure 30 that in these 3 identical tests, contact with paper and contact with brass have each caused an increase in power factor over the values found for oil alone, and that these increases are greater with increasing temperature. These increases are thus not due to oxygen in the oil, and if due to oxygen at all it can only be that absorbed in the metal and on the surfaces of the paper fibers. The values of power factor at four

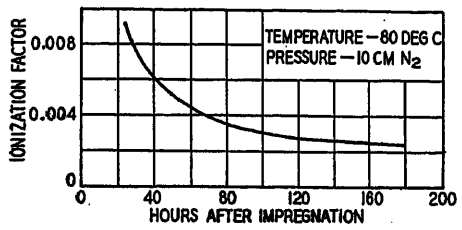

**Figure 26. Ionization factor-time**

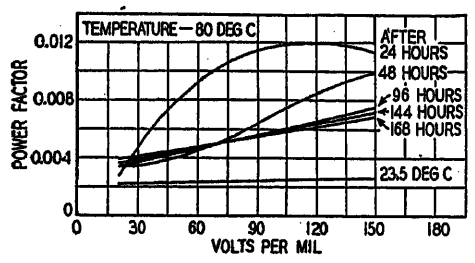

**Figure 27. Power factor-voltage**

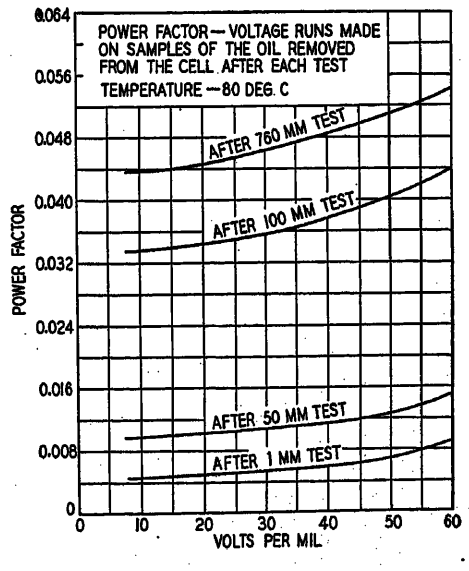
temperatures are given in table IV. The fourth line, "brass and paper" is gotten by adding to the values for pure oil the *increases* in power factor caused by paper and by brass separately. As seen the values obtained by this simple approximate method of computing the joint total effect, agree closely with the measured values on the one-millimeter oxygen sample. In other words, in the latter sample contact with paper and brass alone are sufficient to account for the observed values; the small amount of oxygen present in the one-millimeter oxygen sample, in spite of the high temperature, 80 degrees centigrade, appears to play no part in the observed increases in power factor.



*Ionization in the Process of Oxidation.* Oxidation is very slow at 25 degrees centigrade; power factor voltage curves

**Table IV. Power Factor**

| | 20 Deg. C. | 40 Deg. C. | 60 Deg. C. | 80 Deg. C. |
|---|---|---|---|---|
| Pure oil | 0.00040 | 0.00076 | 0.00150 | 0.00300 |
| Plus paper | 0.00040 | 0.00086 | 0.00180 | 0.00390 |
| Plus brass | 0.00044 | 0.00095 | 0.00220 | 0.00480 |
| Brass plus paper | 0.00044 | 0.00105 | 0.00250 | 0.00570 |
| One-millimeter sample | 0.00044 | 0.00100 | 0.00240 | 0.00545 |

at this temperature for the whole range of oxygen saturation are flat and power factor values for oxygen saturation at 76-centimeter pressure are only about twice those at one millimeter. On the other hand, these differences are greatly increased as the temperature rises, as seen in figure 18. At low saturation (one millimeter and 5 centimeters) the power factor increases linearly with temperature, indicating increasing conductivity, and possibly a linear oxidation increase. However, for higher oxygen contents something else is going on as indicated by the more rapid

**Figure 29. Power factor - temperature**

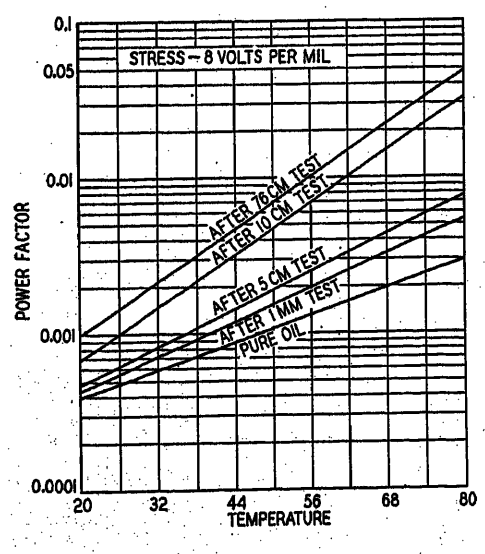


**Figure 28. Power factor-voltage**

rise of power factor with temperature. At 80 degrees the power factor of the 76-centimeter sample is now eight times that of the one-millimeter sample. These variations strongly suggest that the *process* of oxidation itself, as well as the oxidation products, contribute to the measured value of power factor. In order to test this question a sample of oil was thoroughly purified and degassed; then saturated with oxygen at 76 centimeters pressure, and maintained at this pressure and at 80 degrees

centigrade for 65 hours in a glass vessel. It was then admitted to the test cell under the same conditions, and the power factor measured at intervals over a further 72 hours. The sample was then evacuated down to 0.2 millimeter of mercury pressure, thus drawing off the oxygen and volatile oxidation products. Power factor observations were continued over a further 55 hours.

The results are shown in figure 31. Initially, the pure oil had a power factor 0.003 at 80 degrees; saturated with oxygen at 76 centimeters pressure, after 65 hours at 80 degrees centigrade in a glass vessel, the value rises to 0.01. At this value it was introduced into the power factor test cell. As seen from the curve a very much more rapid increase of power factor sets in. This is due to the catalytic action of the brass electrodes. The initial rate of rise is not maintained, however, and the power factor-time curve seems to be approaching a constant value. At 72 hours oxygen and volatile products were removed; the power factor dropped rapidly and within a short time reached a steady value about 25 per cent lower.

Evidently oxidation in the oil causes 2 types of power factor increase, one a permanent change due to nonvolatile products, as indicated in the final steady value of figure 31, and the other due to ions liberated in the process of oxidation, or to an ionized condition of the volatile oxidation products. This second source of ions disappears in the absence of free oxygen. It is known that oxidation may be accelerated by electrochemical processes,[27] indicating that the ions involved in oxidation reactions are associated with the conduction current. Apparently we have something of this kind here.

Power factor-voltage curves taken before and after the oxygen is removed indicate that both elements of power factor increase with increasing stress. Apparently

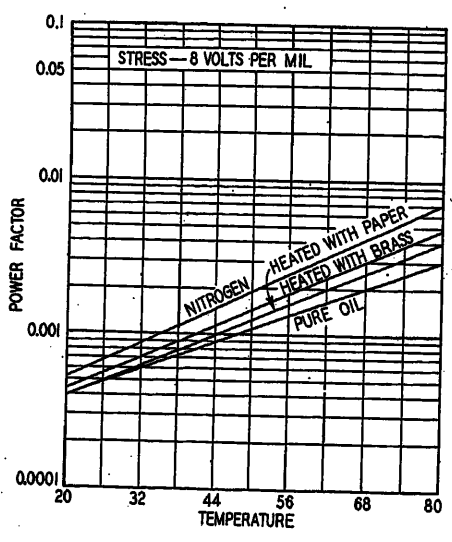

**Figure 30. Power factor - temperature**

the volatile active oxidation ions move faster, or cause more ionization by collision, as the stress increases. The rise of power factor due to the nonvolatile ions has been discussed in an earlier paragraph.

*Catalytic Action of Brass.* The catalytic action of certain metals in accelerating oxidation in oils is well known[27,28,29] though few quantitative studies have been reported. Copper and brass are among the most active metals, and consequently the problem of restricting oxidation in insulating oils is not only that of selecting oils inherently most highly stable against oxidation, but of

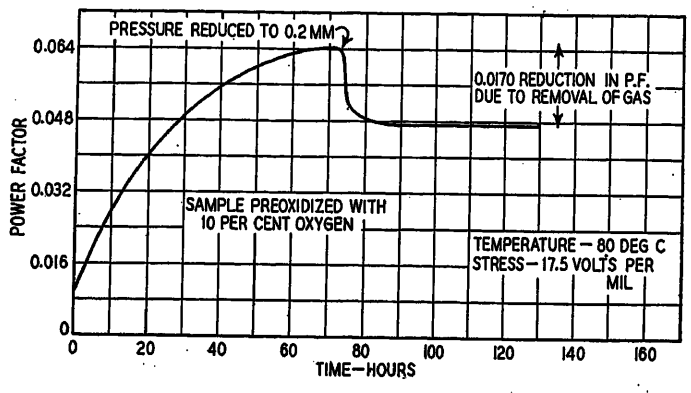

**Figure 31. Power factor-time**

basing this selection on the behavior in the presence of copper. For the contact of insulating oil with copper conductor, or other metal is unavoidable.

In the present work all electrical measurements have utilized brass electrodes. The resulting accelerating influence on oxidation has been evident at several points; for example, the more rapid rise of power factor-temperature curves of the samples containing more oxygen, figure 18. (Note however the apparent absence of the effect at low oxygen content.) In order to obtain evidence of the relative importance of the effect, oxygen absorption tests were run on 2 identical samples of oil, one containing 65 square centimeters of clean sheet brass. Each 1,000-cubic-centimeter sample of degassed oil was placed in a 2,000-cubic-centimeter glass suction flask exposing a surface arc of about 108 square centimeters of oil. The pressure was reduced to 0.1 millimeter, temperature raised to 80 degrees, and dry oxygen admitted at 76 centimeters of mercury pressure; the oxygen was maintained at this pressure and the amount entering each flask was measured at intervals. This amount is a measure of the oxygen entering into chemical combination. The results are shown in figure 32. The rate of absorption in both cases is at first quite rapid, and this probably represents solubility rather than oxidation. There is also some suggestion of an induction period, or delay in the final process, between 30 and 60 hours. The period beyond 150 hours probably best represents the relative rates of oxidation. As seen it appears that the oil alone is approaching a stationary or saturated condition with no further oxidation. The sample containing brass, however, is still absorbing oxygen rapidly indicating continuous auto-catalytic oxidation.

The general trend of the power factor-time curves of paper impregnated at high oxygen content, is much the same as the upper curve of figure 32. Other results, for example the higher power factors of paper layers next the electrodes, also indicate the powerful influence of the

brass electrodes, in the presence of appreciable amounts of oxygen, on the rates of oxidation, and consequent changes in electrical properties. The results throughout therefore involve not only oil oxidation, but especially oil oxidation in the presence of a metal catalyzer. This, however, is essentially the condition prevailing in practice. The separate influence of the oil alone is evident in several studies, but in view of the above facts, becomes of lesser interest for the practical problem. Further studies of autocatalytic action will be essential for complete understanding and control of oxidation deterioration in insulating oils.

## Conclusions

Accelerated oxidation tests have been made on an insulating oil, with oxygen introduced over the range 0.013 to 10.4 per cent, by volume. Similar tests were made on wood pulp paper impregnated with the oils with oxygen content maintained. The outstanding conclusion

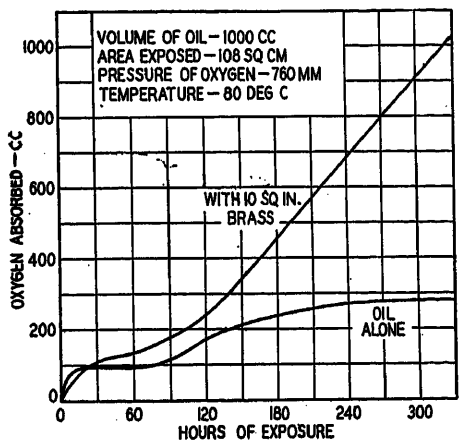

**Figure 32. Oxygen absorption-time showing the catalytic effect of brass**

of the work is the relative unimportance (over the duration of the tests—200 hours at 80 degrees centigrade), of small amounts of oxygen as a cause of change of electrical properties.

1. At impregnating pressures up to 5 centimeters of oxygen (0.7 per cent volume content) the electrical properties of impregnated paper show little or no instability due to oxygen content.

2. Power factor values and changes found in specimens impregnated in oxygen at one millimeter pressure, are completely accounted for by changes in the oil due to contact with paper and with metal electrodes in practically complete absence of oxygen.

3. Impregnation in oxygen at one millimeter pressure results in better characteristics than impregnation in air at the same pressure apparently due to the greater solubility of oxygen than of nitrogen.

4. A critical range of impregnation pressure is found between 5 centimeters and 10 centimeters (0.7 to 1.5 per cent volume content of oxygen). Power factor values increase rapidly with oxygen content, and also with time. Beyond 10 centimeters the rate of these changes falls off; at 76 centimeters a saturation condition represented by constant high values is indicated.

5. The *process* of oxidation in oil is a source of increased liquid or gaseous ionization, and of consequent increased dielectric loss in both oil and impregnated paper. Withdrawal of oxygen and volatile products causes large and immediate reduction of power factor.

6. Rising power factor voltage curves are found for all oil and impregnated specimens at 80 degrees. The rise is more rapid in specimens in which oxidation is in progress than those from which all gas has been withdrawn after oxidation. All such curves are flat up to 150 volts per mil at 25 degrees centigrade.

7. The change of power factor with temperature above 30 degrees centigrade is the most sensitive indicator of oxidation—better, for example, than the power factor-voltage relation.

8. Oxidation and deterioration of the oil is greatly accelerated by the catalytic action of brass. The behavior of impregnated specimens may be largely influenced by this effect.

9. Power factor tests of paper layers following oxidation runs show no increase in layers next the electrodes in the one-millimeter specimens, a very slight rise for the 5-centimeter specimens, and a definite rise above average values only for oxygen contents above 0.7 per cent by volume (5 centimeters pressure of oxygen impregnation).

10. The evidence of these tests is that the continued process of oxidation rather than the products of oxidation is the cause of oil and paper deterioration. Small amounts of oxygen either combine or go into solution without serious impairment of electrical properties.

# Discussions

## Of AIEE Papers—as Recommended for Publication by Technical Committees

ON THIS and the following 13 pages appear discussions submitted for publication, and approved by the technical committees, on papers presented at the 1937 summer convention, Milwaukee, Wis., June 21–25; the Pacific Coast convention, Spokane, Wash., August 30– September 3, 1937; and the North Eastern District meeting, Buffalo, N. Y., May 5–7, 1937. Authors' closures, where they have been submitted, will be found at the end of the discussion on their respective papers.

Members anywhere are encouraged to submit written discussion of any paper published in ELECTRICAL ENGINEERING, which discussion will be reviewed by the proper committee and considered for possible publication in a subsequent issue. Discussions of papers scheduled for presentation at any AIEE meeting or convention will be closed 2 weeks after presentation. Discussions should be (1) concise; (2) restricted to the subject of the paper or papers under consideration; and (3) typewritten and submitted in triplicate to AIEE headquarters, 33 West 39th Street, New York, N. Y.

## The Saturated Synchronous Machine

**Discussion of a paper by B. L. Robertson, T. A. Rogers, and C. F. Dalziel published in the July 1937 issue, pages 858–63, and presented for oral discussion at the electrical machinery session of the Pacific Coast convention, Spokane, Wash., September 2, 1937.**

**R. H. Park** (The Calco Chemical Company, Inc., Bound Brook, N. J.): The following analysis of saturation phenomena which was worked out by the writer a year or so ago in an effort to develop a simplified yet adequate theory of saturation effects in salient-pole synchronous machines is submitted as discussion of Messrs. Robertson, Rogers, and Dalziel's paper with the thought that they or others may care to check experimentally the theoretical developments presented.

It should be unnecessary to point out that any useful theory must represent a good compromise between precision and convenience, and with this thought in mind it is believed that we are warranted in considering the usefulness of the assumption that the field pole tips and faces of salient-pole machines may be regarded, for purposes of calculation as not being subject to saturation effects, despite the fact that we recognize the fact that in many cases pole-tip saturation effects do exist to an at least appreciable extent.

With this assumption which will be utilized in what follows, and the further rather implied assumption that there is no significant saturation in the quadrature axis, we note that whatever the field below the pole faces there will be a definite magnetic potential between adjacent pole faces and that the magnetic field in the air gap will be the same as it would be if the rotor were unsaturated and the field current had some appropriate value say $I$ different from its actual value with saturation which we will designate as $I_s$.

Now as to the effects of stator saturation we may note that these may be thought of as equivalent to introduction into an unsaturated stator of suitable counter magnetomotive forces arising where the stator flux density is a maximum and producing a resultant distortion of the stator and air-gap fluxes relative to what would otherwise obtain.

We shall at this point introduce the postulate that the effect of this counter magnetomotive force may be regarded with sufficient accuracy as being equivalent to the effect of an added space fundamental component of armature current say $i_{sc}$ where

$i_s$ = actual (space vector of) armature current

$i$ = equivalent unsaturated armature current
$= i_s + i_{sc}$

Thus we will have

$I_{sc}$ = saturation component of field current
$= I_s - I$ (1)

$i_{sc}$ = saturation component of armature current
$= i - i_s$ (2)

Evidently by virtue of our definitions of $I$ and $i$ they must specify the magnetic state of the air gap, and hence the torque, these being what would obtain with these currents and no saturation.

As a consequence of our postulates we note that $I_{sc}$ must depend wholly on the value of flux in the pole, hence only on $I$ and $i_d$, i.e., in general $I$ = funct $(I, i_d)$ where the function in question may be specified in terms of a series of zero-power-factor curves.

But also the fluxes emanating from the pole face and between the pole tips tend to be substantially linearly related to $I$ and $i_d$ while there will be a general tendency for the fluxes emanating below the pole tips to be proportional to $I$, and hence there will be a tendency for $I_{sc}$ to be exclusively a function of a linear function of $I$ and $i_d$, i.e., it will be approximately true that

$$I_{sc} = F(\Phi) \quad (3)$$

where

$\Phi$ = *effective per unit field flux*

$$= I - ki_d \quad (4)$$
$$= \psi_d + x_{fs}i_d$$

$k$ = a constant

$x_{fs} = x_d - k$
= *field saturation reactance*

As regards the saturation component of armature current, in a stationary armature machine this may be assumed to be associated and in space phase with a flux $\bar{\phi}$ which is intermediate in size and phase between the space fundamental armature flux linkages and the air gap flux $\psi + x_l i_s$ so that we may assume in general that

$$i_{sc} = f(\bar{\Phi}) \quad (5)$$

where

$\bar{\phi}$ = effective per unit armature flux
$= \bar{\psi} + x_{as}i_s$

$x_{as}$ = *armature saturation reactance* (6)

though for most practical purposes it is possible that we could assume $x_{as} = 0$ with little error.

Evidently the character of the functions $F$ and $f$ may be determined by tests respectively at high field, low terminal voltage, and low field high terminal voltage and the results so obtained utilized for computing excitation under any arbitrary head conditions.

Just as we recognize that $\bar{\phi}$ is nearly equal to $\bar{\psi}$ so we may readily recognize that $\Phi$ will be nearly equal to the field linkages $\bar{\Psi} = \psi_d + x_d'i_d$, so that it would be expected that $x_{fs}$ is approximately equal to $x_d'$. Actually $x_{fs}$ must exceed the *saturated* value of $x_d'$ at any value of $\Phi$ since if $i_d$ is varied so as to hold $\Psi$ constant it will be evident from a consideration of the detail flux conditions in the pole that $I_{sc}$ will increase as $I$ increases.

Since $x_d'$ is known to vary considerably with saturation the suggestion is clear that $x_{fs}$ may and in fact should be assumed, in general, to vary with saturation. That is, we may take $x_{fs}$ = funct $(\Phi)$, a procedure which at once increases the range of validity of equations 3 and 4. Obviously $x_{as}$ could also be treated as a function of saturation. However this would appear to be an unnecessary refinement.

Tests to determine the variation of $x_{fs}$ with saturation are easily carried out by simply comparing the no-load and full-load saturation curves, after making allowance for stator saturation, and we see, therefore, that to the extent that stator

saturation may be ignored $x_{fs}$ is in reality identical with Potier reactance. This demonstrates that in general Potier reactance must tend, except for the effect of stator saturation, to equal and in fact to exceed transient rather than leakage reactance a fact which seems to have frequently escaped recognition. On the other hand Potier reactance, as ordinarily defined, is not identical with $x_{fs}$ since it does not make allowance for stator saturation, a circumstance which is believed to account in the main for the very large variations with saturation at high values of armature voltage which were reported in a recent paper by March and Crary.

To show an application of the theory developed we may note that under ordinary load conditions it does not appear that armature saturation of revolving field synchronous machines is of great influence on stability, and that in any case, if we disregard armature saturation, the steady state coefficient of synchronizing torque $I_s = dT/d\delta$

where

$\delta$ = displacement angle

and

$$T = \text{per unit torque} = i_q\psi_d - i_d\psi_q = i_qI - (x_d - x_q)i_di_q \quad (7)$$

is

$$T_s = i_q\frac{dI}{d\delta} + \{I - (x_d - x_q)i_d\}\frac{di_q}{d\delta} - (x_d - x_q)i_q\frac{di_d}{d\delta} \quad (8)$$

But for a machine connected to an infinite bus of voltage $e$ (external impedance included in machine constants) there is

$$(r^2 + x_dx_q)i_d = x_q(I - e\cos\delta) - r\,e\sin\delta \quad (9)$$

$$(r^2 + x_dx_q)i_q = r(I - e\cos\delta) + x_de\sin\delta$$

while since $I_s$ is assumed constant

$$\frac{dI}{d\delta} = -\frac{dI_{sc}}{d\delta} = \left\{\frac{\partial I_{sc}}{\partial I}\frac{dI}{d\delta} + \frac{\partial I_{sc}}{\partial i_d}\frac{di_d}{d\delta}\right\} \quad (10)$$

$$= a\frac{di_d}{d\delta}$$

where

$$a = \frac{-\dfrac{\partial I_{sc}}{\partial i_d}}{1 + \dfrac{\partial I_{sc}}{\partial I}} \quad (11)$$

Then if we introduce the quantity

$x_{ds}$ = *saturated synchronous reactance* $= x_d - a$

we find after some transformations

$$\frac{di_d}{d\delta} = \frac{e(x)_q\sin\delta - r\cos\delta)}{r^2 + x_{ds}x_q} \quad (12)$$

$$\frac{di_q}{d\delta} = \frac{re\sin\delta - x_{ds}e\cos\delta}{r^2 + x_{ds}x_q}$$

results which in conjunction with (8) and (10) permit ready evaluation of $T_s$ for any value of $\delta$.

For $r = 0$, for example, we find in detail

$$T_s = \frac{Ie\cos\delta}{x_d} + \frac{x_d - x_q}{x_dx_q}e^2\cos 2\delta + \frac{x_d - x_{ds}}{x_dx_{ds}}e^2\sin^2\delta \quad (13)$$

only the first 2 terms of which are retained in the absence of saturation.

In the special case in which $x_{fs}$ is assumed constant we have from (3) and (4)

$$\frac{\partial I_{sc}}{\partial I} = F'(\Phi)$$

$$\frac{\partial I_{sc}}{\partial i_d} = -(x_d - x_{fs})F'(\Phi)$$

$$a = \frac{(x_d - x_{fs})F'(\Phi)}{1 + F'(\Phi)}$$

which as saturation is sufficiently increased approaches in the limit $a = x_d - x_{fs}$, corresponding to $x_{ds} = x_{fs}$.

## Surge Protection of Distribution Systems

**Discussion and authors' closure of a paper by J. K. Hodnette and L. R. Ludwig published in the June 1937 issue, pages 683–8, and presented for oral discussion at the lightning protective equipment session of the summer convention, Milwaukee, Wis., June 24, 1937.**

**Herman Halperin** (Commonwealth Edison Company, Chicago, Ill.): I presume that the upper of the 2 curves marked *C* in figure 2 is for deion gaps and the other curve is for arrester gaps. Do the characteristics in figure 2 hold substantially for all voltage ratings?

Over 90 per cent of our 4,000-volt overhead distribution system has solid interconnections between the neutral of the 3-kv arrester and the secondary neutral, which is grounded to water pipes on the customers' premises. As a safety measure, the transformer case is not grounded. Our experience is that about one-quarter of one per cent of the transformers fail annually due to lightning even with this interconnection. Most of these are in older transformers, but occasionally a modern one fails. This experience tends to create some doubt in our minds as to the possibility of obtaining a comparatively high degree of protection if protector tubes with initial discharge voltages of 9 times normal voltage were used in place of the arresters that discharge at much less than half those values, except as applied to specially designed transformers.

Referring to the authors' expectation that the maximum surge currents on distribution lines "would be of the same order as those obtained on high-voltage transmission lines," this is not confirmed by measurements of arrester discharge currents, using surge crest ammeters. We have installed surge-crest-ammeter links in the ground lead of 3-kv arresters at about 320 scattered locations over the city of Chicago. During the years 1934–36 the links indicated sizable arrester discharge currents in 121 cases. In most cases the currents were less than 1,000 amperes, in 44 cases the currents were between 1,000 and 5,000 amperes, and in 6 cases the currents were from 5,000 up to 9,000 amperes, the maximum value.

Referring to the third paragraph of page 685, a few recent measurements in Chicago have indicated roughly the same order of surge current through adjacent phase and neutral arresters, indicating that the lightning discharge current divides rather evenly through several arresters that may be installed at one location on a 3-phase overhead line or circuit.

The arrester manufacturers have found from laboratory tests that modern distribution arresters can withstand surge currents greatly above 5,000 amperes, and this is substantiated by operating experience. It is gratifying, however, to learn of the authors' development of a device that can withstand successfully surge currents of the order of 50,000 amperes.

**W. H. Cooney** (General Electric Company, Pittsfield, Mass): The authors have outlined in a very comprehensive manner the surge voltages and currents which may be expected on distribution circuits and their views as to the requirements which protective devices must meet in order to provide a good quality of service.

The time-voltage curves shown in figure 2 are very interesting. Although it is not definitely stated, it appears that curve *A* on the "breakdown characteristics of distribution transformer insulation" is on a "single shot" basis, since curve *B* shows the probable voltage levels at which deterioration of insulation begins with repeated impulses. At one microsecond curve *A* shows a breakdown strength about 27 per cent higher than at 2.5 microseconds, a greater increase of strength with decrease of time than that shown by Messrs. Bellaschi and Teague,[1] but of about the same order as that shown by V. M. Montsinger[2] in his discussion of the Bellaschi and Teague paper.

The probable voltage level at which deterioration begins is shown by the authors as curve *B*, which is 90 per cent of curve *A* for time greater than 2 microseconds. This may be compared with Montsinger's discussion[2] which showed a corresponding representative value of 80 per cent, with a variation from 70 to 90 per cent depending on the kinds of electrodes used in the tests. It should be noted that the authors' curve *B* at one microsecond has dropped to 83 per cent of curve *A*.

Considering all data at present available, it appears that a deterioration level of 90 per cent is somewhat optimistic and that the probable value lies nearer 80 per cent.

The authors refer again to a ratio of impulse crest to 60-cycle crest breakdown of 2.2. Montsinger[2] has shown that such a ratio may range between 1.75 to 2.2 (depending on the type of electrodes) for repeated impulses, a variation sufficient to indicate that the ratio is a band rather than a definite value. In addition, now that data have been presented showing an increase of transformer insulation impulse

strength below 2 microseconds, a so-called impulse ratio has even less significance.

It would appear from figure 3 and from Mr. H. M. Towne's comparison of previously published Deion gap data with the data in figure 2 and table 1, that the authors consider satisfactory a very small margin between the performance of the protective device and the demonstrated strength of the transformer. While protection can be demonstrated by an AIEE impulse test with a new transformer it is doubtful whether this initial margin will be adequate for the deterioration due to repeated impulses and other conditions of service. The authors show that at one microsecond (figure 2) the deterioration level is 83 per cent of the impulse breakdown strength.

While a properly maintained and protected transformer should retain its initial impulse strength indefinitely in service, past experience has indicated that deterioration may occur on some percentage of distribution transformers in service. Some operating companies have recognized this fact by applying to transformers taken out of service only about 65 to 75 per cent of the original factory high-potential test.

It is not generally considered economically feasible to give distribution transformers the degree of maintenance and inspection given to substation and power transformers. As a result, some portion of the transformers in service may have low oil levels, thus exposing parts which are dependent on oil for full insulation; water may enter even into sealed transformers due to failure to close covers tightly after opening for inspection, tap change, etc.; and excessive overloads may be carried to the point of carbonization of insulation. Any of these factors tend to lower the impulse strength of the transformer.

In order to avoid trading on the margin of strength above the demonstrated value it would seem essential to provide a wide margin between the demonstrated impulse strength of the transformer and the voltage levels permitted by the protective device, in view of the effect of repeated impulse voltage and the possibility of deterioration of impulse strength in service.

**L. G. Smith** (Consolidated Gas, Electric Light, and Power Company of Baltimore, Baltimore, Md.): In reference to section 4 on normal frequeny requirements of lightning protectors, it is believed that the lightning arrester designer should give the operator applying lightning arresters accurate data based upon numerous tests of the actual cut-off of the arrester. While it is the practice of the manufacturers to rate arresters in terms of maximum 60-cycle voltage which can be applied to the arrester, this voltage rating is below the actual maximum cut-off voltage of the arrester by some margin of safety. Unfortunately the margin of safety assumed by the various designers is extremely variable. It is believed that this margin has gradually been reduced in recent years by most arrester manufacturers. For this reason it is quite important that operating engineers applying arresters have definite test data showing the actual maximum cut-off voltage of the arrester.

As an example of the need for this information, the operating company may have used arresters of a certain rating on their system for a number of years with satisfactory results and it may be that the particular arrester on which the operating results were obtained had a considerable margin between its rated voltage and the maximum cut-off voltage, which margin may have contributed to the satisfactory operation of the arrester. Based upon this operating experience arresters of another type having a reduced margin of safety may be installed and arrester failures result, due to inability of the arrester to cut-off. In view of the fact that the characteristics and possible overvoltages vary with different systems and are not consistent for various lines on a given system, it is quite essential that the operating engineers have complete information on arrester characteristics so that they can apply arresters intelligently.

**H. M. Towne** (General Electric Company, Pittsfield, Mass.): The authors have presented a very interesting paper on a vitally important subject. The adequate protection of distribution systems from lightning has been given quite thorough study over the past 10 years, and practical operating benefits from these studies have been pyramiding over several years.

The problem of protection of distribution transformers involves many important aspects. First, the protective scheme must be simple and economical. Second, the degree of protection should be liberal—allowing ample margin between the discharge level of the protective device and the impulse strength of the transformer insulation after years of service involving the usual influences of excessive overloads such as possible carbonization and release of water; poor oil, or other weakening of insulations; moisture; any of which may occur on a percentage of transformers in service. Third, this liberal margin of protection should be realized as far as possible under the rare cases of steep wave and high-current lightning discharges, without sacrificing too greatly in the protection level or other factors of security for the greatly predominant, year in and year out, nominal discharge duty. Fourth, the overvoltage protection should not interfere with conventional and recognized good practices in primary fusing and overcurrent protection. Fifth, the lightning protective device should function so as to minimize any hazard of primary power voltage and current on the secondary or consumer's circuit—i.e., afford the greatest possible preservation and protection to that transformer insulation which separates the low voltage consumer circuit from the dangerous high voltage primary circuit—and minimize the primary power voltage or current reaching the secondary circuit attending the discharge of the primary lightning protective device.

Considerable has been written about the desired level of protection to allow for various factors not always present in limited laboratory demonstrations. In the August 1929 *Electric Journal*, A. L. Atherton stated:

> "The criterion should be not merely that a complete failure is not brought about by a single application of surge voltage, but that no damage is done." "Tests have been made . . . using surge voltages covering a wide range of both magnitude and duration, using a variety of insulating materials and making literally millions of observations as a means of securing both limiting and average values to cover the variations which are inevitable in small insulation samples. The indications are that the damage to insulation begins at possibly 2.5 times the value which would be used at line voltage, taking into account the factors of safety normally used in apparatus design for 60-cycle strength. Service experience where there has been opportunity to observe the lightning damage for several years unprotected and then protected has shown that about 90 per cent of the lightning damage is removed by this arrester (3-kv maximum arrester for 2,400-volt circuits) having 3.5 ratio. The modified auto-valve arrester (also for 2,400-volt circuit protection) with a ratio of 2.5 instead of 3.5 . . . has been observed . . . after a few thousand arrester years service no case of apparatus damage has been recorded. . . . Service records have been made with average transformer installations, including both old and new; and with various relations between transformer rating and line insulation."

In the AIEE paper "Development of the New Auto-valve Arrester" presented in January 1930, the authors, Dr. Slepian, Tanberg, and Krause state:

> "Extended tests in the laboratory on insulation protected with arresters have indicated that there is probably no deterioration of insulation with arresters having ratios not exceeding 2.5."

In discussing lightning arresters in the February 1930 *Electric Journal*, Edward Beck states:

> "A good lightning arrester should have a ratio of not more than 4 to 1." . . . "In the new autovalve arrester, ratios of 2.5 and less are secured. . . ."

Again, in the May 1930 *Electric Journal*, Dr. Fortescue discusses the general problem of protection and states:

> "Years of experience with . . . protective ratio between 3 and 3.5 have proved that approximately 90 per cent of the lightning troubles . . . are removed. . . . Several thousand arrester years of field experience with arresters employing a protective ratio of 2.5 has not brought to light any failures of apparatus thus protected. This experience very strongly substantiates the conclusion . . . that the protective ratio of 2.5 is the ideal. . . . It is generally

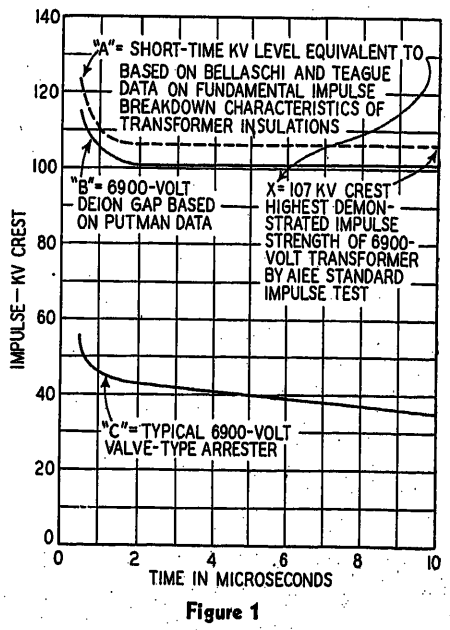

**Figure 1**

accepted that fibrous insulation—which constitutes a large part of the insulation of the transformer—will in course of time deteriorate when subjected to surges above 2.5 times the rating repeatedly. If the surges do not rise above this value, the life of the transformer is indefinitely long."

In view of what was apparently a very extensive study of the fundamental behavior of apparatus insulations in general, in both laboratory and field, as evidenced by these fairly recent articles advocating not more than 2.5 to 1 ratio, it is somewhat difficult to reconcile the present statement by Messrs. Hodnette and Ludwig that "a high degree of protection is obtained with a ratio of protective device discharge to normal frequency voltage of 9 to 1." To avoid trading on the factor of safety above the AIEE demonstrated test strength and also to allow for insulation deterioration which may occur over years of service due to the causes previously cited, it would seem that a much better degree of protection than 9 to 1 is highly desirable.

The authors' curves, figure 2, do not permit a clear understanding of the co-ordination and margin of protection. As pointed out by the authors, knowledge of the insulation strength of transformers to impulse voltages is necessary to intelligently co-ordinate and successfully apply protective devices. Since the curves are all to a percentage ordinate, it is difficult to gain the relationships on a kilovolt basis, utilizing the known demonstrated strength of the transformer insulations. One approach to the co-ordination picture is to start out with the demonstrated impulse test voltage, which is all the purchaser of a transformer knows about its lightning strength. As shown in the authors' table I, a purchaser knows that a 6,900-volt distribution transformer will withstand the 107-kv crest maximum test voltage of the AIEE standard impulse test for the $1^1/_2 \times 40$ full-wave condition. From this 107-kv full-wave test plotted at 6 or 10 microseconds, a curve for the short-time kilovolt strength of the transformer can be plotted using recently published data on the fundamental impulse characteristics of combined solid and liquid transformer insulations.

Messrs. Bellaschi and Teague have discussed the short-time impulse breakdown strength of transformer insulations in their AIEE paper "Dielectric Strength of Transformer Insulation" published in the January 1937 ELECTRICAL ENGINEERING. Their comprehensive investigation shows that the impulse breakdown strength of combined solid and liquid transformer insulation is but little, if any, higher for one-half microsecond to breakdown than at the full $1^1/_2 \times 40$ wave. They show average of tests to breakdowns on test samples, of 300 kv at 0.35 microsecond; 300 kv at 2.5 microseconds; and 280 kv at full 40 microseconds, and they state "these tests for a large number of repeated impulses confirm the constant strength over the impulse region even down to the very short times as previously established." Their curves, figures 6 (for insulation breaking down at around 140-kv crest), and 7 (for insulation breaking down at around 220-kv crest), show that the impulse breakdown is flat from 10,000 microseconds down to about 1 or 2 microseconds and then turns up slightly with the breakdown at 0.5 microsecond being only 12 to 16 per cent higher kilovolt value than for the full $1^1/_2 \times 40$ wave strength. Applying these fundamental data by Bellaschi and Teague to the known 107-kv test, the accompanying curve *A*, figure 1 is obtained, and such a curve should represent the lightning strength for all waves and equivalent to the 107 kv highest demonstrated test on AIEE full $1^1/_2 \times 40$ wave. Whatever margin of safety exists between the 107-kv full-wave test and actual breakdown could logically be expected to exist for the short time equivalent portion of the curve. Such a procedure results in an impulse level below which lightning stresses should be limited to avoid encroaching or trading on the factor of safety above the known demonstrated strength of the transformer.

While Messrs. Hodnette and Ludwig do not give an actual impulse volt-time breakdown curve for the deion protector, such curves were given by Mr. Putman in the February 1937 *Electric Journal*. By adding Mr. Putman's data for the discharge level of the 6,900-volt deion protector as curve *B* to the accompanying figure 1, it appears that the margin of protection to the insulation of a new 6,900-volt transformer is relatively small—unless the factor of safety in transformer insulation above its required AIEE demonstrated strength is quite wholly depended upon.

The authors show in their figure 2 that insulation deterioration from repeated impulses alone begins at about 90 per cent of the $1^1/_2 \times 40$ full wave strength, and they state that this factor is applicable to the figures in table I. Since table I highest test level of a 6,900-volt transformer is 107 kv, the limit above which repeated impulse stresses might cause deterioration is 90 per cent of 107 or 96 kv. It would, therefore, appear that the 102-kv discharge level (Putman's data) of the 6,900-volt deion gap would result in deteriorating stresses.

In discussing the deion gap the authors state that a series resistor, is used to limit the magnitude of the large power follow current, but no data are given regarding the ohmic value. Apparently the protection level of the device involves first the impulse breakdown voltage of the gap (Curve *B* of the accompanying figure 1) and then an *IR* voltage drop due to the discharge current through the series resistor. In evaluating the impulse protection level it is of course necessary to consider this *IR* drop which will exist as long as discharge current flows, which may be many microseconds. For instance, if the series resistance is 5 ohms, an *IR* drop of 100 kv will occur with a 20,000-ampere discharge current. A one ohm resistor would allow an *IR* drop of 50 kv at 50,000-ampere discharge current. On the other hand a one ohm resistor would seemingly be far too low to cause any appreciable reduction in the large power-follow current. Assuming a location of the transformer at a point on the feeder or branch circuit having a line to ground short-circuit current of 1,500 amperes root-mean-square, the line impedance would be 6,900/1,500, or 4.5 ohms, and a one-ohm resistor would only reduce the line to ground short-circuit power follow current through the deion gap from the 1,500 to 1,240 amperes root-mean-square. Similarly, if the transformer were located closer to the substation where a 3,000-ampere short-circuit current is available, a one-ohm resistor would only reduce the short-circuit power-follow current from 3,000 amperes down to 2,100 amperes root-mean-square. Any 6,900-volt sectionalizing fuse link up to 40-ampere rating will be melted in $^1/_2$ cycle at approximately 800 amperes root-mean-square. Then, assuming as low as 1,500 amperes available line short-circuit current, it would appear that the series resistor would have to be at least 4.5 ohms to avoid blowing a 40-ampere sectionalizing fuse or 18.5 ohms to avoid blowing a 15-ampere sectionalizing fuse. The authors may be willing to state the ohmic value of the series resistor and clarify its effects.

The curve *C* of figure 1 shows the discharge level and margin of protection which may be had with a typical 6,900-volt valve-type arrester applied with interconnection.

Such a margin of protection avoids dependence on the undemonstrated factor of safety and also allows for the possible service conditions and abuses which over years of operation may depreciate the transformer-insulation below its demonstrable strength by AIEE test when new.

The authors have cited considerable information on discharge current requirements of protective devices. Probably the most significant data on the required discharge capabilities of distribution system protective devices is the direct measurement of actual lightning current magnitude through individual distribution arresters on distribution systems of various voltage classes, by Mr. H. W. Collins, and also Mr. McEachron and Mr. McMorris. Out of 500 measurements, Collins found 20,000 amperes to be the highest discharge current. McEachron and McMorris data over more than 2 years, involving about 2,800 arrester-years of observation and about 1,000 measured discharges, shows only 2 discharges of 50,000 amperes, or 0.2 per cent. This means one 50,000 ampere discharge out of 1,400 arrester years, and a probability of a single arrester receiving 50,000 amperes discharge once in 1,400 years. 99.8 per cent of the measurements were below 22,000 amperes, and about 97 per cent were under 10,000 amperes. These data show that arresters with discharge capabilities of even 25,000 amperes will give highly satisfactory service performance, and that the authors' contention that 50,000 amperes discharge capacity will give satisfactory results is quite conservative. It is particularly significant that the highest measured discharge current has been proved to be well within the capabilities of available valve-type arresters such as the Pellet type; that is, modern arresters are withstanding the current magnitudes, current durations, the steep wave fronts, the multiple or repetitive stroke, the switching surges, etc., and giving protection to very old as well as new transformers.

While some types of earlier arresters gave some troubles from moisture, corrosion, etc., the modern arresters over the past 4 or 5 years are demonstrating an extremely low mortality rate from all causes.

The valve-type arresters, of course, discharge the short time lightning currents and at the same time prevent any dangerous primary power follow current from reaching the transformer tank and low voltage secondary service.

The authors' paper is a definite contri-

bution to the subject of transformer protection. It is obviously desirable that continued and concerted efforts be directed by the large manufacturers, as well as utilities, toward attaining a complete understanding of lightning protection requirements for virtually complete protection of distribution systems.

**C. S. Sprague** (Purdue University, Lafayette, Ind.): The authors have presented an interesting summary of the range of lightning exposures and of the characteristics of transformer insulation and of protective equipment under 60-cycle and impulse stresses.

Curve *D* of figure 2 brings out the inadequacy of the rod gap in protecting transformer insulation in the range from 6,800 to 13,800 volts. Apparently at still higher voltages the gap would be almost worthless for short-time impulses unless set at a considerably reduced spacing.

In figure 3 the comparison between Deion gaps and valve-type arresters does not seem to be applicable unless interconnection is used with the valve-type arresters. If interconnection is not used the effect of lead and ground impedance would be to materially raise the upper limits of the band between the 2 curves *D*. Although the lightning arrester with interconnection, provides a considerably lower impulse voltage than the deion gap, it should be kept in mind that the duration of the wave is considerably longer with the valve-type arrester.

At first glance it seems from figure 3, that the valve-type lightning arrester may provide relatively greater protection, in spite of the authors' closing statement that both types provide adequate protection as demonstrated by field records. This is particularly noticeable in the 11,500 volt and the 13,800 volt range where the deion gap impulse break-down voltage (curve *E*) is quite close to the minimum impulse strength (curve *C*). By reference to curves *A* and *B* of the authors' figure 2, it would appear that the voltage permitted by the deion gap is dangerously close to the value which will produce deterioration of the insulation. Perhaps the short duration of the voltage will account for the adequacy of protection claimed for the deion gap.

**J. K. Hodnette** and **L. R. Ludwig**: Complete protection of distribution system and the apparatus connected to them is the aim and object of distribution engineers. The manufacturer contributes to this program by continually improving distribution transformers and protective equipment, and by the accumulation of data on surge protection. It was the object of this paper to present data to enable a more intelligent use and application of distribution equipment toward this end. Data has been presented on transformer insulation and lightning arrester requirements so that operating engineers could get a broader picture of this important problem.

It has been pointed out in the paper that it is necessary to provide protection under the worst conditions which result from direct, or near direct, strokes of lightning rather than the average condition. In the past, much of the data on protective devices and distribution system protection have been obtained by field trials in the large metropolitan distribution systems. With the rapid expansion of distribution systems in rural areas these data are proving inadequate. As was pointed out by Mr. F. E. Andrews, currents much in excess of those formerly expected appear on distribution systems relatively often as evidenced by damage to cutouts, insulators, and other equipment. In most cases evidence of direct strokes on distribution systems is centered about apparatus damage. This emphasizes the fact that it is the conditions of direct strokes, or near direct strokes, to the line rather than induced surges which result in the major damage to distribution systems. It is imperative, therefore, that the protective equipment be designed for the worst conditions. Field experience has indicated that it is necessary to have a discharge capacity of 100,000 amperes to prevent damage from lightning.

Figure 2 of the paper presents data on the impulse characteristics of distribution transformer insulation as compared to characteristics of protective devices. In view of the large amount of discussion on this subject further explanation of this figure is given. The data, from which curve *A* representing the breakdown characteristics of distribution transformer insulation was drawn, were determined by tests on actual distribution transformers and supplemented by tests with models. In comparing this curve with previously prepared data, it should be noted that the time lag is plotted from the start of the voltage wave instead of the time lag above the 60-cycle breakdown value which has been the conventional method in the past. This curve was derived by applying impulse voltages and increasing them in steps until the transformer insulation failed. In this respect it is not a one-shot breakdown curve. Curve *B* was determined by applying impulse voltages slightly under the minimum strength and observing the effects. It is quite difficult to accurately establish values at short time lags due to the fact that the testing technique for testing short waves has not been completely developed. Also the variation in individual samples may be misleading. Much data is necessary in order to completely establish a curve of this nature. Points that were determined were established by applying short steep-front waves to distribution transformers and chopping them by a gap flashover. Repetition of this process established points below which the insulation would not fail.

With reference to the ratio between the impulse breakdown voltage, and the 60-cycle breakdown voltage, the ratio of 2.2 applies to a well balanced insulation structure. This value is generally applied to the ratio between the 60-cycle breakdown strength and the minimum impulse breakdown strength. This ratio does not hold for all insulation structures but depends upon the type of insulation and the electrodes used. Values considerably lower and higher than 2.2 have been found on special insulation structures. The data in the paper, however, applies to distribution transformers.

Insulation deterioration under impulse voltages appears to be associated with the formation of corona. Where the design is such as to eliminate or minimize the formation of corona, deterioration does not occur, or the voltage at which it does occur approximately coincides with the breakdown voltage. Corona under oil occurs at relatively high voltage stresses. The minimum voltage required to produce corona is in general in excess of the operating and test voltages applied to distribution transformers as covered in the paper. For this reason deterioration of the insulation of distribution transformers by impulse voltages takes place very near the ultimate breakdown level. In this connection the tests made by Messrs. Bellaschi and Teague, referred to by Messrs. Towne and Cooney, were made on insulation structures for power transformers and under conditions which would permit the formation of corona. In this respect distribution transformers are in a class by themselves, and the laws applying to the insulation of high-voltage power transformers do not necessarily apply to distribution transformers, due to the discontinuous nature of insulation curves at short spacings.

There is a decided difference in opinion among engineers regarding the deterioration of insulation of distribution transformers in service. Mr. Cooney states that a properly maintained and protected transformer should retain its initial impulse strength indefinitely in service. We agree with this statement. Past experience, however, has indicated that the mortality rate of old transformers is higher than those that have been in service a few years. This has been due largely to the deterioration of bushings and cables. Previously it was common practice to depend upon the cable insulation to a large extent in insulating the primary leads from the transformer case. Exposure to weather reduced this insulation so that failure of the bushings resulted at a much lower value. The coils, however, being submerged in transformer oil and protected from moisture and oxygen deteriorated very little. Also, these transformers were so designed and protected that no protection was afforded the secondary windings against overvoltage surges. Modern transformers are built with bushings of adequate size so that it is not necessary to depend upon the cable lead insulation, and balanced protection now prevents damage to the high-voltage as well as the low-voltage windings.

Moisture in oil has often been referred to as the cause of deterioration of distribution transformer insulation. A large percentage of the distribution transformers in service at the present time are operating with water in the bottom of the transformer cases. Modern distribution transformers are made tight which prevents the entrance of water and helps to protect the oil from excessive oxidation.

Excessive overloads have been referred to as the cause of insulation deterioration and ultimate failure. The deterioration strength of transformer insulation does not materially decrease until the temperature is reached which produces a chemical change in the insulation. This is usually evidenced by formation of gases. Sustained temperatures lower than this result in loss of mechanical strength but no rapid deterioration of the insulation. Thermal protective devices are available for use in dis-

tribution transformers which will eliminate the possibility of damage from this source. These devices, in the form of thermally operated circuit breakers, are placed in distribution transformers and adjusted so as to disconnect the transformer when the winding reaches a predetermined safe temperature.

It is apparent, therefore, that a great deal has been done in the design and construction of modern distribution transformers to prevent deterioration of any of the vital insulation members even after many years of service.

Until recent years, the accepted method of protecting distribution transformers against lightning was to connect lightning arresters to the primary leads and ground them to separately driven grounds. As pointed out by Mr. Sprague, the voltage to which the transformer was subjected was not only the discharge voltage of the arrester but the drop in the ground leads and in the ground resistance. Instead of limiting the voltage to 10 or 15 kv on a 2,400-volt transformer, it rose to 100,000 or 200,000 volts or more, depending on the grounding conditions and nature of the surges. Experiments have indicated the possibility of developing as high as 10,000 volts per linear foot in lightning arrester leads.

This represented the conditions in 1929 and 1930, when the 4 papers were written which were cited by Mr. Towne. These papers indicated the ratio of 2.5 as being ideal, and above which deterioration began. In this connection it is interesting to note that the first attempt to rationalize transformer insulation from the standpoint of surge voltages was made by Vogel in 1932 ("Factors Influencing the Insulation Coordination of Transformers," AIEE TRANSACTIONS, volume 52, June 1932, page 411). Past experience with arresters having a ratio of 3.5 had reduced lightning troubles by 90 per cent. It is apparent that under the existing conditions it was only necessary to get more experience to determine that the ratio of 2.5 reduced the troubles due to lightning by only 90 per cent. The uncontrolled factors were the dominating ones in 10 per cent of the cases. In other words, lightning arresters protected against small induced surges but offered no protection against direct or near direct strokes. The introduction of balanced protection eliminated the uncertain factors of lead drop and ground resistance drop, and reduced the problem of lightning protection to a scientific basis. We are still confronted, however, with the problem of protecting apparatus against maximum conditions of surge voltages which have always been the cause of apparatus damage and system outages. This can be accomplished with protective devices, connected to give 3-point protection and having adequate surge current discharge capacity, which limit the voltage to a value below the breakdown strength of the insulation under all conditions. The curves in figure 3, assume this balance protection and show that the margin between the insulation strength and discharge voltage is satisfactory. Laboratory tests under direct stroke conditions prove this fact ("Direct Stroke Protection of Distribution Transformers," by H. V. Putman, *Electric Journal*, February 1937). Field experience confirms it.

It is difficult to compare a conventional valve type arrester with the deion arrester since they have such widely different characteristics. The deion arrester is essentially an arc-discharge device which bypasses the surge current. The lightning arrester on the other hand, is an energy absorbing device depending on the energy to establish the cut-off voltage. Some lightning arresters have a resistance discharge characteristic so that the discharge voltage increases with increasing current. It is not possible to determine the maximum voltage which would be sustained from the characteristics as determined by the relatively low AIEE test. The deion arrester, since it is an arc-discharge device, has a very low sustained voltage. It is equipped with a series resistor to prevent system disturbances in the cases when there is a flow of dynamic current following flashover. This resistor adds little to the sustained voltage under abnormal conditions since it is provided with a shunt gap which flashes over at high surge currents removing it from the path of the surge current. Under these conditions the deionizing action set up by the surge current appeases the establishment of any dynamic follow current. These devices are insulated to withstand and receive the AIEE acceptance dielectric tests for distribution transformers.

Mr. Towne has aptly stated that practical operating benefits have been pyramided over several years, as a result of a thorough study of the protection of distribution systems from lightning. It is believed that additional benefits can be derived by applying the knowledge so far gained on transformer insulation and the frequency and intensity of lightning stroke currents. We should not compromise on this problem but strive to protect apparatus against the maximum conditions to which it is subjected. As a protective ratio of 2.5 to 3.5 was considered adequate in the past when we had to deal with the uncertainty of lead and ground resistance drops, it would seem only logical that a higher ratio would be satisfactory with these uncertainties removed. This can be done without danger of apparatus failure, and would result in better system protection, better protection to the consumer through a more adequately insulated and a more rugged and serviceable protective device.

## Distribution Lightning Arrester Performance Data

**Discussion and closure of a paper prepared by the lightning arrester subcommittee of the AIEE committee on protective devices published in the May 1937 issue, pages 576–7, and presented for oral discussion at the lightning protective equipment session of the summer convention, Milwaukee, Wis., June 24, 1937.**

**Herman Halperin** (Commonwealth Edison Company, Chicago, Ill.): The lightning arrester subcommittee also has prepared a general guide for use by utilities in testing lightning arresters. In this connection, the data on new arresters in the June 1937 ELECTRICAL ENGINEERING will be found helpful. The guide should be of particular value in testing line-type arresters rated at 15 kv and less which are removed from lines.

For the past 4 years, we have been testing used 3-kv arresters in Chicago before they are returned to stock for reuse. About 85 per cent of those that were mechanically satisfactory have been found electrically suitable for additional service. These tests have all been made with 60-cycle supply.

In connection with the guide, it is hoped that some utilities will make impulse as well as 60-cycle tests in order to determine what correlation exists between the 2 types of tests in indicating defects.

**L. G. Smith** (Consolidated Gas, Electric Light, and Power Company of Baltimore, Baltimore, Md.): These data are of value and necessary in applying arresters intelligently. However, it is hoped that these data will be expanded in the future so as to cover additional lightning arrester characteristics so essential for the correct application of arresters. In view of the fact that solid insulation is subject to a wide range of surges including those of very steep wave front and those of very high current it is highly desirable to know the voltage that will be passed by the arrester for all types of surges, including those of very steep wave front and for surge currents up to the point at which the arrester element flashes over. The ideal application of lightning arresters is one in which the arrester will always fail before the equipment protected, since the arrester represents a much smaller economic loss than for that which it protects.

**I. W. Gross** (American Gas and Electric Company, New York, N. Y.): In this report on distribution arrester characteristics, we have for the first time, to my knowledge, a rather complete over-all picture of the expected performance of present day commercial distribution arresters.

A study of the data in table I shows that in the distribution arrester class *variations* in terminal voltage, both on initial breakdown, and under discharge conditions, of the order of 30 per cent may be expected. This situation which, I take it, is due largely to manufacturing tolerances which it is not feasible to overcome economically, should be recognized in applying lightning arrester protection not only to transformers of present design but also to those now in service, if satisfactory results are to be expected.

There is one thing that should be pointed out in connection with the impulse voltage permitted by these distribution arresters, and that is, they permit some 30 to 70 per cent higher voltage across their terminals on breakdown than they allow during discharge at 1,500 amperes. And yet these voltages at breakdown are at a comparatively low rate of voltage rise, namely, 50 to 100 kv per microsecond as specified in the present AIEE standards. These same standards provide for rates of rise of some 1,000 kv per microsecond in the 115- to 138-kv class of arresters. It is hard to believe that natural lightning is so temperamental that it impresses voltages of 1,000 kv per microsecond on high-voltage lines and takes pity on the distribution systems in the 3-

to 9-kv class and reduces its destructive effects to a 50 or 100 kv per microsecond pattern.

In addition I wish to suggest that all lightning arrester manufacturers give data on their arresters on a common basis, that is, on the basis of average, maximum, or minimum voltage characteristics both for breakdown and *IR*-drop characteristics, with expected tolerances stated.

In closing, it is hoped the committee will continue its work in collecting and presenting authentic data of this type on arresters in the higher voltage classes in both the distribution and station types. Such information is decidedly helpful in applying protection to equipment with a reasonable degree of certainty that it will work in actual practice. It cannot be too strongly emphasized that such data are absolutely necessary in attempting to apply the lightning arrester as a protective device to a great deal of the equipment now in use, where such equipment has been weakened with age, or of older design not having the insulation strength of apparatus bought today.

**J. R. North:** Mr. Gross's constructive suggestions regarding desirable improvements in the Institute Standards for Lightning Arresters and test procedure are most welcome. Table I in the report shows a wide range between the minimum and maximum performance characteristics of different makes of arresters. The gap breakdown voltage is of the order of 130–150 per cent of the average *IR* drop, with rates of rise of 50–100 kv per microsecond.

The voltage rating of arresters represents the maximum allowable dynamic voltage across the arrester terminals under any conditions. As mentioned by Mr. Halperin, reports prepared by the lightning arrester subcommittee discussing testing procedure, application of arresters, and specific protection practices have been prepared and will be distributed to members of the protective devices committee and other interested parties.

It is hoped next year to be able to present a report containing similar performance data pertaining to station type arresters and to line type arresters rated above 15 kv.

## Expulsion Protective Gaps

**Discussion and authors' closure of a paper by W. J. Rudge, Jr., and E. J. Wade published in the May 1937 issue, pages 551–7, and presented for oral discussion at the lightning protective equipment session of the summer convention, Milwaukee, Wis., June 24, 1937.**

**E. J. Allen** (General Electric Company, Pittsfield, Mass.): The engineering data given in the paper sets forth the principal operating characteristics of expulsion gaps, based on 5 years' experience, and augmented by intensive development in the laboratory and field.

By way of explanation, the ordinate of the curves, on figure 10 in the paper, is plotted in terms of "'length of flame feet" which, of course, is visible, and was scaled from photographs of staged tests. These photographs were taken during power current interruption of corresponding crest currents shown on abscissa. This "length of flame" versus "current" interrupted relationship is practically independent of circuit voltage rating.

Also of equal interest, however, is the length of electrically conducting gases within the flame during power current interruption by the tube. The length of electrically conducting gases is an important consideration when applying expulsion protective gaps in service, to prevent these expelled gases from contacting other nearby metal parts of dissimilar potential, and thereby avoiding risk of faulting other phases. For example, conducting gases from the line end of an expulsion tube should not come in contact with nearby grounded metal structures; likewise the gases from a design having a grounded end of the tube should not come in contact with any line conductors, which of course, are insulated from ground.

However, the proximity of metal objects to the path of the discharge gases is not as serious a limitation to the successful service applications of expulsion protective gaps as might be anticipated. Tests have shown that the length of the electrically conducting gases extending from the open end of the tube during power current interruption never exceeds the length of flame. For example, during field tests on a 132-kv system, a grounded metal pipe was located 6 feet, 10 inches from the "tee" discharge deflectors located on the line end of the tube. With this set-up during power current interruption of 11,300 crest amperes by the expulsion gap, the arc did not follow the flame to ground. At distances of 6 feet or less, a power arc was maintained between the discharge deflector and grounded metal pipe. At 11,300 crest amperes power current interruption, however, the length of flame is approximately 9 feet. Hence in this particular series of tests, the length of the electrically conducting gases extended only two-thirds of the distance between the "tee" vent and the visible length of flame.

Typical tests such as described above indicate that the length of electrically conducting gases within the flame envelope attending power current interruption by the tube bears a complex relationship, as this depends not only on the current, but mainly on circuit voltage characteristics and design of the discharge deflectors.

It is believed, therefore, that the curve, figure 10 in the paper, can be safely used when applying expulsion protective gaps to obtain adequate clearance from electrically conducting discharge gases, thereby avoiding risk of faulting other phases. In practice, the expulsion tube can either be positioned in such a way as to provide necessary clearance of discharge gases using straight vents from the tube or if not, the path of the expelled arc flame can be diverted by means of "tee" (90 degrees) or Y (45 degrees) discharge deflectors attached to the lower electrode.

Another point mentioned in the paper concerns the rapid expulsion action of the tubes, and resultant power current interruption before system relays can function. The "First Report of Power System Stability" by the AIEE subcommittee on interconnection and stability (ELECTRICAL ENGINEERING, February 1937, page 261) recognizes that special tube-type protectors of a design described in the paper will increase the practical operating power limits.

System stability, or the ability of a system to stay together during a disturbance, is an important factor toward improving continuity of service. Line disturbances caused by lightning flashover of insulators with attendant load rejection will quite naturally tend to cause instability of transmission systems operating near the power limit. Even with ultrahigh-speed relaying and breakers on the faulted line, not equipped with protector tubes, the system is subjected to this disturbance for at least several cycles. Tests have shown that interruption of rated power current through an expulsion gap occurs within a cycle. Hence their net effect, by preventing flashover at the protected structures, is to reduce system outages and extend the stability limit, or power transmitting capacity of the system.

**R. L. Thomas** (Pennsylvania Water and Power Company, Baltimore, Md.): Too much emphasis cannot be placed on the statement made by the authors that proper mountings for expulsion gaps are absolutely vital. In a tabulation in the authors' paper there are statistics covering the operation of expulsion gaps on a 69-kv line of the Pennsylvania Water and Power Company in 1935 and 1936. Actually the statistics cover the line from Holtwood to Safe Harbor (Lehmans Farm switching station) owned by Pennsylvania Water and Power Company and the line from Safe Harbor to Lancaster (Engleside) which is owned by Pennsylvania Power and Light Company. The record for 1935 shows 4 tube failures and 16 trip-outs. A footnote states that "The cause for these failures has been determined and remedied."

Briefly, the remedies applied or changes made were first, the external gap was increased from 5 inches to 11 or 12 inches; second, a shielding ring was placed around the outside of each tube near the lower end; third, the horns were shortened; and fourth, an attachment was added to the mounting to prevent the turning of the tube mounting with respect to the insulator string and at the same time to allow the tube to swing with the insulator string.

There were no tube failures in 1936 and we thought the problem had been solved. However, on June 14, 1937 there was another tube failure. The circuit switches were reclosed 4 times but in each case there was another trip-out and the circuit was left out of service. It was several hours before the trouble could be located and remedied. It was found that on one of the tubes on a strain tower the fastening bolts had slipped in the slots provided for adjustment and that on this particular tube the horn had not been shortened sufficiently and the movement caused the horn to approach the conductor instead of increasing the external gap.

The failure shows the importance of carefully designed and ruggedly constructed mountings. Otherwise a device which is

intended to eliminate a large number of short time interruptions may actually cause a relatively long time interruption.

I do not want to introduce a note of discouragement since with any new device it is natural that all of the things that can happen cannot be foreseen. There were no tube failures in 1936 and naturally we hope that there will be no more in the future.

**L. G. Smith** (Consolidated Gas, Electric Light, and Power Company of Baltimore, Baltimore, Md.): The authors state as a requisite for the operation of these gaps that they have a lower flashover than the line insulation. While from a design standpoint this co-ordination is readily obtained, in actual installations care is necessary in that it is possible in the case of improper application to so distort the dielectric field that either co-ordination between the gap and the line insulation is destroyed or the co-ordination between internal and external flashover is lost. In tests it has been found that both of these are possible, namely, that external flashovers and insulation flashovers have resulted without an internal breakdown of the gap. The authors mention the possible use of these gaps on ungrounded neutral systems. Until more definite data are available on the ability of these gaps to clear the very low currents that would exist in the case of breakdown from phase to ground it is believed that such applications are questionable. In addition to this, should an arcing ground occur on one phase the voltage might rise to sufficiently high values on other phases to cause numerous tube flashovers.

The setting of the external gaps, particularly on lower-voltage tubes is quite important where the external gap is quite small. Our company, which has applied these tubes on 13.2-kv wood pole lines has had a few cases where expansion and contraction of the cross-arms due to alternate wetting and drying may account for as much as one-fourth inch change in dimension, thus causing the mountings to loosen and short the external gap. One case of tube failure attributed to this cause has actually been experienced. It is hoped that the possibility of trouble of this type has been eliminated by the change in the design of the mounting bracket, which includes 2 spurs which are forced into the crossarm. In addition to this some trouble has been experienced on strain poles where stranded line conductors were attached to the crossarm through strain insulators in which the the unwinding effect of the stranded conductor caused the strain insulators to rotate, moving the loop over the crossarm into the arcing rod, shorting the external gap. This trouble has been corrected by installing 2 pin-type insulators, one on each crossarm and relocating the tube so that the arcing rod points at the conductor between the pin type insulators, which carry the loop over the top of the crossarm.

While it is desirable to install expulsion protective gaps on every structure on high-voltage lines such a practice becomes quite expensive on low-voltage lines. If satisfactory operating results can be obtained a more economical installation would consist of installing these gaps on only a fraction of the total number of structures. In order to do this successfully it is necessary to have reasonably low ground resistance on those poles on which the gaps are installed and to maintain an insulation level as high as possible on those that do not have the gaps. As shown in table I in the paper we installed gaps on every second pole on one 2-circuit line and on every third pole on another line in 1935. In 1936 gaps were installed on another double circuit line on every fourth pole. No trip-outs due to lightning on any of these lines have been experienced. There was one trip-out due to tube failure resulting from shorting the external gap. There were 2 other cases of tube failure without trip-outs due to the shorting of the external gaps. In 1935 we installed a similar device of another manufacture on a single-circuit 13.2-kv line. In 2 years' operating experience no trip-outs due to lightning have occurred on this line. It is interesting to compare this operating experience with the operating experience prior to the installation of the gaps. On feeders number 87 and 88, the 3-year period prior to the installation of gaps in 1935, one feeder tripped out 5 times, 4 of which were due to burning down of the conductors and the other feeder tripped out 5 times, all 5 trip-outs, being due to conductor burn-downs. On feeders 60 and 61 which were equipped with gaps on every fourth pole in 1936, in the 4-year period prior to 1936, one circuit had 7 conductor burn-downs and the other circuit 5, all due to lightning. In the single-circuit lines, which were equipped with tubes of another manufacture in 1935, this line tripped out 3 times due to lightning in the 3-year period prior to 1935. We plan to install devices of this kind on another double-circuit line with the tubes installed on every sixth pole. In all of these installations we are raising the impulse level of the ungapped poles to 700 kv. We are attempting to determine the maximum spacing of devices of this kind for use on 13.2 kv consistent with a material reduction in trip-outs. Obviously the lower the cost per mile for such installations the more miles of line that can be equipped.

It is believed that if satisfactory weathering characteristics are obtained with devices of this kind they have a real future in increasing reliability of service.

**L. R. Ludwig** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): Messrs. Rudge and Wade presented in their paper a tabulation of operating companies who have utilized self-clearing protector tubes. The authors are correct in stating that the tubes have given very satisfactory results in the field. Attached is a list of further applications of these devices, which have been made during the past few years, also with satisfactory results.

The authors have stated that the problem of applying these protector devices is one of determining the short circuit currents and the recovery voltage. While it is relatively a simple matter to determine the short circuit current, the problem of determining the recovery rate is much more involved.

Mr. Evans and Mr. Montieth have made a very considerable contribution in this field by utilizing the calculating board in a novel manner for obtaining with the oscillograph an actual trace of the recovery voltage as it will occur on any given system.

Referring to the authors' figure 1, it is to be noted that the tube is of unsymmetrical design with respect to the electrodes. It would be expected that breakdown at the 2 polarities would be different on this account and the authors are requested to state if this is the case. Furthermore, since an inserted lower electrode has been omitted, it is conceivable that a certain amount of difficulty may be experienced with this design due to external flashover of the tube rather than internal flashover. It will be interesting to inquire if difficulties of this kind have been obtained.

**H. G. Brinton** (General Electric Company, Pittsfield, Mass.): In the case of oil circuit-breakers where the whole circuit is cut off, the value of capacitance may be quite small and the recovery rate very high but the device is capable of operating with very high recovery rates. On the other hand the safe operation of the expulsion gap calls for a less rapid recovery rate, but the recovery rates are lower because the circuit capacitance at interruption of the current is larger. Ordinarily the recovery rate on expulsion gaps is of the order of 100 to 300 volts per microsecond.

Figure 9 of the Rudge-Wade paper shows a sudden kick or rise in the arc voltage just before the arc broke, caused by a sudden increase of arc resistance. The arc voltage kicks up to about twice its previous value and the current drops to zero more rapidly. The voltage on the gap then reverses suddenly when the current comes to zero, be-

**Table I. Installations of Delon Protectors, Type L**

cause the current was lagging and so the current and arc voltage were negative when the generated voltage was positive.

The voltage recovery rate in figure 9 is considerably steeper than that obtained in single gap line to ground operation where the current was smaller and more nearly in phase with the generated voltage. The more rapid recovery rates are usually associated with larger short circuit currents. It is an interesting characteristic of the expulsion gap that the larger currents and consequently greater evolution of exhaust gases enable it to clear with greater recovery voltages.

**W. J. Rudge, Jr., and E. J. Wade:** The discussions of our paper are particularly valuable in that they not only lay emphasis on the importance of many points mentioned in the paper, but add to the total operating experience which may be critically examined by those interested in the application of protector tubes.

Both Mr. Smith and Mr. Thomas have endorsed our statements as to the importance of properly mounting hardware for tubes. Mr. Smith's data on the comparative performance of feeders, both before and after they were equipped with tubes, is particularly helpful because it gives a better understanding of the improvement in line performance which can be obtained through their use. While from a theoretical point of view, tubes should be located on each structure to obtain best protection, Mr. Smith has shown that tubes located on every second, third, or fourth structure can effect a material improvement in line performance. This type of experience is needed by the industry, as it will enable an economic evaluation of the improvement in line performance which can be accomplished with different densities of installations. By employing such schemes it appears possible to effect a material improvement in line performance in a great many cases where economic considerations indicate that it is impractical to equip every structure.

Mr. Ludwig's discussion with the attached table is useful in that it gives an idea of the number of companies which are interested in the application of tubes. However, it is to be regretted that the data does not include the operating experience with the tubes, since tubes are comparatively new devices and it is necessary to build up a back log of experience which will be helpful in both the design and application of tubes.

The calculating-board methods described by Messrs. Evans and Monteith will no doubt be helpful in examining numerous circuit arrangements which cannot be easily obtained by field measurements. It must be realized, however, that before the calculating board results can be fully relied upon, that sufficient data from field tests on the actual circuits as they are in service must be obtained in order to establish the constants used on the calculating board. Experience in the past with models in the laboratory, particularly in the study of lightning, has shown that extreme care must be exercised when interrupting results obtained from studies on models rather than the full scale structures found in service. While we have made numerous calculations and studies of circuit recovery voltages, it is our feeling that greater confidence can be placed in the results by obtaining measurements on full scale models such as are found in service. It is for this reason that we have developed the equipment and pursued a program of making field tests to obtain this necessary fundamental information.

Mr. Ludwig has asked if the unsymmetrical design with respect to the tube electrodes caused by the omission of an inserted lower electrode is responsible for the external flashover of the tubes. Our tests to date have indicated that the insertion of a lower electrode alone does not carry with it the assurance that external flashovers will not obtain. It is truer, however, that the assembly and design do have an influence on the positive and negative impulse characteristics of the tube.

We wish to thank those who have taken part in the discussion of our paper and urge all operators who are obtaining experience with tubes to keep records on their performance so that they may be made available to the industry, as in this way a more complete picture may be had as to the relative merits of tubes and their ability to improve the performance of transmission circuits.

## Flashover Characteristics of Rod Gaps and Insulators

**Discussion of a report of the subcommittee on correlation of laboratory data of the EEI-NEMA joint committee on insulation coordination published in the June 1937 issue, pages 712–14, and presented for oral discussion at the lightning protective equipment session of the summer convention, Milwaukee, Wis., June 24, 1937.**

**C. S. Sprague** (Purdue University, Lafayette, Ind.): This report presents data which are evidently the result of a considerable amount of work by 5 of the larger high-voltage laboratories of the country. The calibration of such easily reproducible apparatus as the insulator string and the rod gap should be of considerable advantage in checking the satisfactory operation of equipment and testing technique. Even though the insulator string and rod gap are rapidly losing caste as protective devices due to their impulse characteristics at very short times and the data is subject to a tolerance of 8 per cent, this does not seriously affect its usefulness for the above purpose.

Tables I and II show some apparent minor inconsistencies. For instance in table I, for suspension insulators with the 1 × 5 wave, the negative wave values are higher than those for the positive wave over the range of 12 units shown. With the 1.5 × 40 wave, the negative values are lower up to 12 units, at which points the curves apparently cross, the negative values being higher from 13 to 20 units.

However in table II for the rod gap, with the 1 × 5 wave the negative values are considerably higher except in the range from 8 to 20 inches where the positive and negative values are essentially the same, but with one point at 15 inches showing the negative value to be lower. For the 1.5 × 40 wave the negative values are considerably higher over the whole range, which is in contrast to the 1.5 × 40 wave data on the suspension insulators.

There is admittedly a considerable physical difference between the insulator string and the rod gap, and perhaps, in view of the 8 per cent tolerance, the above inconsistencies are more apparent than real. However, the writer would ask if there is, as yet, any satisfactory explanation of the preceding trends of the data of tables I and II.

In further reference to table I, will the 8 per cent tolerance apply to the values as given, for all 10-inch disks at $5^{3}/_{4}$-inch spacing, regardless of size or type of insulator cap and other hardware?

From figure 1, it appears that we now have a much needed correction for the effect of humidity. Years ago we talked of the relative humidity. Then there was found to be a correlation between spark-over values and the absolute humidity, and the latter was expressed sometimes as grams per cubic meter, and sometimes as grains per cubic foot. Now we have the correction factor plotted against the absolute pressure of the water vapor. While the writer has no particular preference as to how the water content of the air is expressed, it is hoped that a unified terminology can be adopted.

**P. H. McAuley** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): A review at this time of the technical details leading to the satisfactory agreement in data from different laboratories seems appropriate. The outstanding items which contributed to this agreement are:

1. Use of cathode-ray oscillograph and resistance voltage divider as a method of voltage measurement.
2. Adoption of standard waves by all laboratories.
3. Determination of correction factors chiefly for humidity of the air.

Previous to 1929 the usual method of making high-voltage impulse tests was to set up a generator circuit, calculate the wave form by approximate methods and measure the peak voltage with a sphere gap. With the capacitors available, poor regulation naturally could not be avoided with changes in the capacity of the test piece. The importance of the oscillations due to generator inductance and stray capacity was not appreciated. These oscillations varied with load and resulted in inconsistent and abnormally high values. Fielder and Torok applied the cathode-

**Table I. Comparing Early Trafford Impulse Data on Suspension Insulators With Values From the Committee Report**

| Units | 1929 | 1937 |
|---|---|---|
| 4 | 425 | 440 |
| 6 | 605 | 610 |
| 8 | 780 | 780 |
| 10 | 945 | 945 |

| 14 | 1,260 | 1,265 |
| 16 | 1,425 | 1,425 |

ray oscillograph with a resistance voltage divider to a 2,000-kv impulse generator at Trafford in 1928. The practice of determining the volt-time characteristic curve of high-voltage insulation was adopted immediately and the sphere gap was practically discarded for impulse measurements. Our first field curve above 1,000 kv, dated November 1928, was on 10 suspension insulators and shows a minimum value of 920 kv and a one microsecond value of 1,510 kv. The most recently published data gives 945 and 1,500 kv for these points. However, this accuracy within 3 per cent in 1928 was partly due to compensating errors. The humidity was not even recorded but was probably around 0.15 inches of mercury. A 5 per cent positive error in the divider system was later discovered and probably compensated for most of the humidity correction. The wave form was far from smooth but the fundamental happened to be close to 1.5 × 40 and positive.

It is interesting to compare the values from the committee report with the time

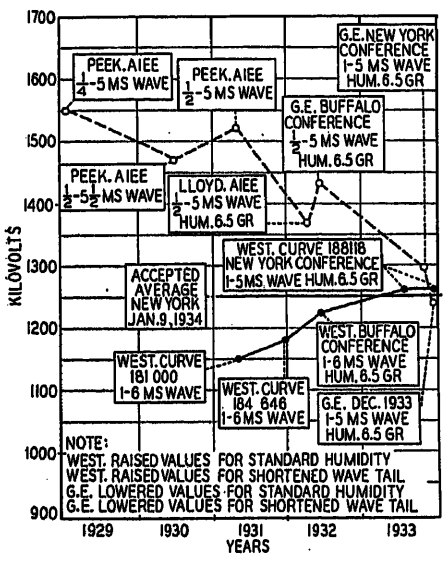

**Figure 1. History of laboratory co-ordination, 11 standard insulators, positive short waves**

log curves published in *Electrical World*, November 23, 1929 and in the AIEE TRANSACTIONS, July 1930. Insulators only are considered, as the present form of rod gap had not been adopted. The agreement in table I indicates the soundness of the measuring methods used at Trafford nearly 8 years ago.

A few years later this system of voltage measurement had benefited from a number of technical improvements chiefly on the cathode-ray oscillograph. Complete calibration curves for some of the sphere gaps based on measurements with the oscillograph were made and presented by Fielder (*Electrical World*, September 30, 1933). The effect of air conditions was realized and data on correction factors were collected. Standard waves were adopted in co-operation with other laboratories. Thus was made possible the correlation of laboratory data regardless of whether the sphere gap or the oscillograph was depended upon for voltage measurement. Many problems still remained and much time was required to collect and co-ordinate data on different apparatus. However, the technical obstacles had been solved experimentally. Then and not till then were reliable mathematical methods of impulse generator circuit analysis present.

The steps and progress in laboratory co-ordination are well illustrated by figure 1, showing different values obtained for minimum short wave flashover of 11 suspension insulators. Changes in wave form, humidity corrections, and measuring methods reduced a spread of 30 per cent to less than 2 per cent over a period of 3 years.

The trend at present to consider negative waves has introduced some more unknown factors and interesting problems. What seems to be needed now is fundamental research of the phenomena of breakdown.

## Lightning Currents in 132-Kv Lines

**Discussion of a paper by Philip Spom and I. W. Gross published in the February 1937 issue, pages 245–52, and presented for oral discussion at the opening session of the North Eastern District meeting, Buffalo, N. Y., May 5, 1937.**

**P. L. Bellaschi:** See discussion, this page.

**S. K. Waldorf** (Pennsylvania Water and Power Company, Baltimore, Md.): Analysis of a recent outage of the Holtwood-York 69-kv line has yielded information closely related to that presented by Messrs. Sporn and Gross. It has particular bearing on the questions of current distribution in transmission towers and the surge impedance of overhead ground wires.

One circuit of the double-circuit line tripped during a severe lightning storm. On patrolling the line, it was found that an arc had occurred between the top phase conductor and the structure of tower 63, and that the surge-crest ammeter links were strongly magnetized on towers 63 and 64. The links on towers 61 and 62 were found magnetized to a less extent. Brackets for the links were mounted on only one leg of each tower and indicated leg currents of 14,600 and 12,200 amperes in towers 63 and 64, respectively. As is customary when estimating the current in a tower equipped with only one pair of surge-crest ammeter links, the tower currents were taken as 4 times the leg currents, or 58,400 and 48,800 amperes in towers 63 and 64, respectively. The currents in the 2 towers being almost equal, it was concluded that lightning had probably struck one or both of the overhead ground wires between the towers.

With the footing resistance of tower 63 being 11 ohms, and the tower current 58,400 amperes, their product yielded a tower potential of approximately 640 kv. This was only about 60 per cent of the nominal flashover value of the line which indicated at first glance that the initial flashover should have occurred elsewhere than at the tower. Following this train of thought, the next possibility investigated was that of a flashover from a ground wire to the line conductor between towers, followed by flashover from the line conductor to tower 63. This seemed a likely sequence of events with the current of 58,400 amperes and the surge impedance of the overhead ground wire causing a potential difference of approximately 29,000 kv between the struck wire and the line conductor. Examination of lightning current observations made on 3 transmission lines since 1934 showed that this hypothesis also was probably incorrect. Numerous cases were found where heavy surge currents had travelled along overhead ground wires without flashover occurring. The circumstance has been repeated so often that the conclusion was inevitable that the surge impedance of an overhead ground wire is something appreciably less than 500 ohms at the point of contact of a lightning stroke.

Messrs. Sporn and Gross have shown that a relation exists between the length of a counterpoise conductor and its relative current-carrying capacity. At tower 63, 50 ohms was the ground resistance of the counterpoise connected to the leg in which the current of 14,600 amperes was measured, and the ground resistance of the other 3 counterpoise wires was 16, 20, and 55 ohms, respectively. The current in the tower was estimated on the assumption that the current carried by each leg varied inversely as the ground resistance of the buried conductor connected to that leg. On this basis, the current in the tower was calculated to be in the neighborhood of 110,000 amperes, which is more than enough to account for the flashover at the tower.

Measurements on towers having surge crest ammeter links on all four legs have shown that appreciable error in measurement can result if only one leg carries links, due to the unequal distribution of surge current between the legs of a tower. When all of the enumerated facts were considered, the conclusion was that the flashover was due to a very heavy surge current in tower 63.

In general, the analysis of this outage has led to an examination of the data collected by the Pennsylvania Water and Power Company from an additional point of view. At this time it is felt that Messrs. Sporn and Gross are correct in questioning the accepted value of 400 or 500 ohms as the surge impedence of a wire near the point of contact of a lightning stroke. Further investigation is being made to establish the effect of counterpoise ground resistance on the distribution of surge current in a tower.

## Probable Outages of Shielded Transmission Lines

**Discussion and author's closure of a paper by S. K. Waldorf published in the May 1937 issue, pages 597–600, and presented for oral discussion at the opening session of the North Eastern District meeting, Buffalo, N. Y., May 5, 1937.**

**P. L. Bellaschi** (Westinghouse Electric & Manufacturing Company, Sharon, Pa.): The considerable field data on lightning currents now available naturally suggest through correlation processes the best design technique to render transmission lines

practically free from lightning outages. A great deal of laboratory and analytical work has been done to establish this development along sound lines. All this is clearly set forth in these 2 papers, yet it is apparent also that new data suggest further analysis. It is with this viewpoint in mind that a method is suggested for evaluating the duration of the lightning stroke discharge from the crest currents measured at adjacent towers.

Thus, lightning upon striking directly a tower of footing resistance $R_1$, discharges a current $i_1$ through it. Consider a current $i_2$ through the adjacent tower of footing resistance $R_2$. The inductance of the overhead wire or wires between the 2 towers is designated as $L$. The corresponding crest values of the currents measured at the two towers are, respectively, $I_1$ and $I_2$.

It has been established from fundamental findings, here and abroad, that the more common type of lightning discharge rises abruptly to crest, receding to low values in a relatively longer time (microseconds). The discharge is apparently unidirectional or quasi-unidirectional in wave form, though there are indications that reversal of the polarity of the current discharge may occur. The exponential wave form, when all is considered, is sufficiently valid for the purpose here and serves well as a first approach in the analysis. That is, considering that the current is

$$i_1 = I_1 e^{-\frac{0.69t}{T}} \qquad (1)$$

it can be shown by relatively simple analysis that

$$i_2 = I_1 \left(\frac{R_1}{R_2}\right)\left(\frac{R_2/L}{R_2/L - \frac{0.69}{T}}\right) \times \left(e^{-\frac{0.69t}{T}} - e^{-\frac{R_2 t}{L}}\right) \qquad (2)$$

The maximum current $I_2$ occurs at $t_m$, i.e.

$$t_m = \frac{\ln \frac{R_2}{L} - \ln \frac{0.69}{T}}{R_2/L - \frac{0.69}{T}} \qquad (3)$$

Then

$$\frac{I_2}{I_1} \cdot \frac{R_2}{R_1} = \left(\frac{R_2/L}{R_2/L - \frac{0.69}{T}}\right) \times \left(e^{-\frac{0.69 t_m}{T}} - e^{-\frac{R_2}{L} t_m}\right) \qquad (4)$$

In applying relationship (4) it is essential that the crest currents should correspond to a lightning stroke directly to one of the towers. Considering values of transmission line constants encountered (such for example, $L = 400$ microhenries; $R_2 = 5$ to 20 or more), and since the ratio on the right hand of equation 4 would hardly or infrequently exceed 0.70 approximately, possible ranging down to 0.10, it appears from the equation that values of $T$ (duration of lightning discharge) range from 10 to 100 microseconds.

Though this preliminary analysis in calculating the duration of the lightning-stroke discharge is subject to a number of obvious criticisms, these hardly should detract from the possibilities new analytical methods of attack present in the study of field data.

**S. K. Waldorf:** Mr. Bellaschi's conclusion that lightning surges are slower in development than has been generally supposed, is borne out by experience. There has been a lack of flashovers on overhead ground wires carrying heavy surge currents, a behavior probably due to the surge impedance of the ground wires being low as a result of the surges not having steep wave fronts.

Since table IV of the paper was prepared, the initial flashover of the Holtwood-York 69-kv line has occurred, which changes the actual lightning outages per year for this line from 0 as given in the table to approximately 0.5. This is in agreement with the value of 0.38 probable outages per year which calculation shows can be expected for this line. The other figures given in table IV remain approximately the same as originally given.

## Heat Transfer Efficiency of Range Units

**Discussion and author's closure of a paper by W. James Walsh published in the August 1937 issue, pages 953–8.**

**W. N. Lindblad** (Pacific Gas and Electric Company, Emeryville, Calif.): Experience gained by the writer in making a number of tests such as Mr. Walsh describes has accentuated the importance of careful measurement and necessary compensation for errors in order that consistent results may be obtained. The use of a drop of oil to minimize evaporation is a unique and no doubt effective method of reducing this rather considerable error.

The over-all efficiency is greatly affected by the amount of water chosen. In a number of tests made by the writer on similar pots and units but with 5 pounds of water instead of 2.76 pounds, appreciably higher efficiencies were obtained. It would be of interest to know why Mr. Walsh selected 1,250 grams as the weight of water used.

The maximum instantaneous efficiencies were assumed by Mr. Walsh to be those coincident with the flat portion of the efficiency curves in figure 7 of Mr. Walsh's paper. It is to be noted that these efficiencies are occurring while the water and presumably the unit are increasing in temperature, possibly at the same rate. It has been the writer's experience that the unit continues to increase in temperature after the water reaches a constant temperature (boiling) and that, consequently, the heat transfer efficiency increases to a value somewhat higher than shown.

The increase in efficiency obtained with black-bottom pots, particularly on the more radiant units, coincides with the writer's experience. Other factors also have a bearing, particularly the concavity of the bottom. With a perfectly flat and bright-bottom pot, the writer has found that the unit $B$ (as labeled in Mr. Walsh's paper) invariably showed higher efficiencies than unit $A$. When the flat bottom was blackened by spraying with lacquer, the efficiency on unit $B$ was reduced considerably, showing that the heat conduction was reduced by the addition of the lacquer.

Tests with pots having a concavity of as little as $^1/_{32}$ inch gave results similar to those of Mr. Walsh's which leads the writer to believe that Mr. Walsh's pots were slightly concave.

It is interesting to note that with a perfectly flat top unit and a flat-bottom pot, over-all efficiencies of 67 per cent and instantaneous efficiencies of over 80 per cent were obtained with 5 pounds of water over a 75 degrees centigrade range of temperature.

**W. J. Walsh:** In regard to Mr. Lindblad's first remark, it may be stated that it was found quite possible to secure consistent results when a good oil film was formed over the water surface. However, there were times when, due to a slight surface contamination on the water, a film refused to form. This difficulty was remedied by taking greater pains in cleaning the equipment used in handling the water.

In connection with methods of minimizing evaporation, the device employed in similar tests performed recently at Oregon State College by Mr. W. G. Short may be of interest. In his tests, Mr. Short substituted a thin sheet of waxed paper (cut to fit the utensil at the water line) for the oil film, and secured even better results without the difficulties attending the use of oil.

In determining the amount of water to be used, the writer was guided principally by the apparent predominance of 2-quart utensils in ordinary cooking operations. In the writer's opinion, the use of larger quantities of water would result, in general, in slightly lower values of efficiency, supposing of course that the utensil diameter remained the same. Further, it appears to the writer that the efficiency values obtained with the larger quantities of water would depend to a great extent upon the ability of the temperature-indicating device employed to give truly representative average temperature values. To be more explicit, one would not use, say, a resistance thermometer with the resistance element spread out in only one plane, but one having the resistance element distributed in both horizontal and vertical planes. It seems reasonable to expect the latter device to give much more representative temperature values than the former when larger quantities of water are used. It would be of interest to know the method employed by Mr. Lindblad in determining his temperature values.

In his discussion, Mr. Lindblad further states that the writer assumed that the maximum instantaneous efficiency was coincident with the flat portion of the efficiency curves shown in figure 7 of the paper. This was not assumed, but definitely justified, as indicated in the paper under the heading "Discussion of Results" (page 957, ELECTRICAL ENGINEERING, Aug. 1937).

Mr. Lindblad also indicates that in his experiments the use of lacquer on the bottom of the utensil reduced the efficiency of heat transfer of the unit labeled $B$ in the

writer's paper. In this connection, it may be pointed out that the thickness of the lacquer layer and the condition of its surface would have a great deal to do with the results obtained. In the writer's experiments, results were obtained which indicated nearly a 3 per cent increase in the instantaneous efficiency of the unit *B* when it was used with the black-bottomed utensil. With a relatively thick layer of lacquer, it should be quite possible to effect a reduction in the efficiency of a unit such as *B*, but in the writer's opinion, a thin, dull-surfaced layer of lacquer would not result in an appreciable reduction in efficiency except on those units operating at a very low temperature.

Mr. Lindblad further points out that the concavity of the bottom of the utensil has a marked influence on the heat-transfer efficiency of surface units. It may also be pointed that a convex bottom has just as great, and probably a greater, effect. Since the utensils used by the writer were intended for actual kitchen use, they were purposely made slightly concave for obvious practical reasons.

In his closing statement, Mr. Lindblad cites certain efficiency values which he has obtained in his experiments. It would be very interesting to know the rating of the unit upon which the tests were performed, and the methods employed by Mr. Lindblad in determining the several necessary quantities involved. In short, a paper by Mr. Lindblad setting forth the results of his experience would be most welcome. The writer would like to take this opportunity to express his appreciation to Mr. Lindblad for his most instructive discussion.

The writer notes with considerable interest the presence of 2 letters to the editor in ELECTRICAL ENGINEERING for October 1937 commenting on the paper. Mr. Wiegand presents several interesting points which will undoubtedly be of value in future work along this line. Of course, the time and financial investment necessary for carrying out such tests as he proposes are practically beyond the range of any but a commercial organization.

The writer notes with particular interest the comments made by Professor Seeley in his letter. Essentially the same ideas were expressed to the writer by Professor F. O. McMillan of Oregon State College at the time that he suggested the subject to the writer.

## Relay Operation During System Oscillations

**Discussion of a paper by C. R. Mason published in the July 1937 issue, pages 823–32, and presented for oral discussion at the development of protective equipment session of the Pacific Coast convention, Spokane, Wash., August 31, 1937.**

L. F. Kennedy (General Electric Company, Philadelphia, Pa.): It is my hope that every relay engineer will thoroughly study Mr. Mason's paper, particularly figures 5 and 6. Familiarity, with the changing relations between current and voltage, is necessary to an understanding of relay performance when the system is in a disturbed condition. We have known that protective systems, with the exception of the differential types, are more or less prone to operation during system swings or oscillations. Mr. Mason has presented the information bearing on relay operation in compact form for the benefit of relay engineers in such a manner that it should be of very material assistance to all relay engineers.

Supplementing the fundamental data showing system performance, Mr. Mason has indicated in general terms the manner in which various types of relay elements may operate. As he states, such conclusions as may be drawn are thorougly obvious from the text.

The use of zero-phase-sequence or negative-phase-sequence relay devices would eliminate any tendency to operate on oscillations or swings. Such relays will not operate to clear simultaneous 3-phase faults. It is most important that 3-phase faults be quickly removed if severe and prolonged oscillations are to be avoided. I have recently reviewed a number of oscillograph records of disturbances on a large Eastern system. A surprising number of these started as balanced 3-phase faults. I am in agreement with most protective engineers who feel justified in demanding that the protective equipment operate with at least the same degree of promptness on these balanced faults as on any other type.

J. H. Neher (Philadelphia Electric Company, Philadelphia, Pa.): Mr. Mason is to be congratulated on his excellent presentation of the complicated factors involved in the analysis of relay performance during out-of-step conditions on a transmission system.

In presenting the operating characteristics of the various types of relays involved, Mr. Mason has employed a somewhat different method than I have used in my paper. I should like to emphasize the point, therefore, that whichever method you prefer to use, that method is equally applicable in determining the performance of the relay under either out-of-step or fault conditions. In other words, the operation of a relay under short circuit conditions may be determined by applying the currents and voltages given in table I of my paper to the characteristic figures in Mr. Mason's paper, and, conversely, the impedance presented to the relay under out of step conditions as determined by Mr. Mason may be plotted against the characteristic impedance circle for the relay as I have described.

In this connection it is necessary to point out that equation 7 in Mr. Mason's paper gives the impedance presented to the relay as a scalar quantity, whereas it must be employed as a vector quantity in the graphical method which I have described. Equation 6 may be readily transformed into a vector expression for impedance and may be written using polar notation as follows:

$$Z\angle\phi_z = = \frac{Z^1}{2}\angle\phi_z' \times \left[(2n-1) - ctn\frac{\theta}{2}\angle 90^\circ\right]$$

This equation when plotted for a given value of $Z'\angle\phi_z'$ and for all possible values of $\theta$ yields a series of parallel straight lines one for each value of $n$ assumed. This is shown in figure 1 of this discussion in which the constants employed are the same as those in Mr. Mason's paper. The plus sign only of the equation has been used and the equivalent effect of the minus sign has

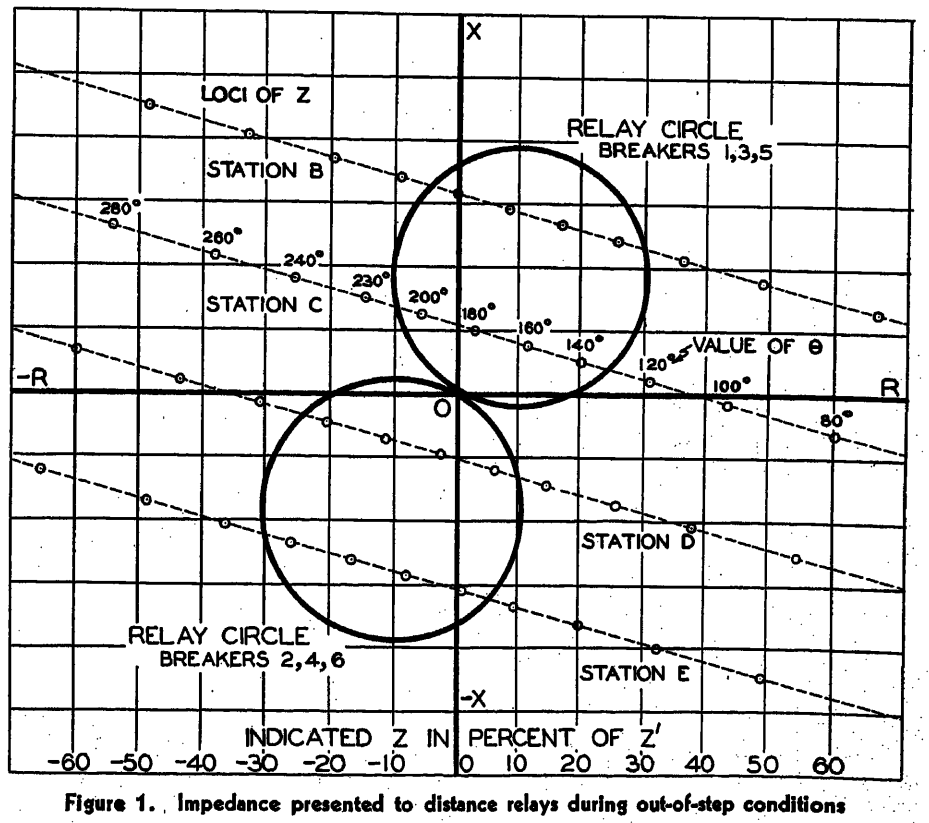

**Figure 1. Impedance presented to distance relays during out-of-step conditions**

been obtained by reversing the relay circle for breakers 2, 4, and 6. Considering the relay operation for breaker 3 at station *C*, as the system pulls out of step with source *A* leading source *F*, the impedance sweeps in from infinity on the right, passes through the relay circle shown (during which time the relay will operate) and then on to infinity on the left, very much in the manner of a comet. The relay operation at the other breakers may be illustrated in a similar manner.

The relay circles shown are those characteristic of directional elements with voltage restraint, but they may be drawn to fit the particular type of element and setting employed. The characteristic circle for a directional element without voltage restraint is a straight line passing through the origin drawn at a slope dependent upon its connections and its internal characteristic angle.

## Capacitance Control of Voltage Distribution in Multibreak Breakers

**Discussion of a paper by R. C. Van Sickle published in the August 1937 issue, pages 1018–24, and presented for oral discussion at the development of protective equipment session of the Pacific Coast convention, Spokane, Wash., August 31, 1937.**

**J. B. MacNeill** (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The uneven distribution of voltage between breaks of a metal-tank circuit breaker has been known for several years. This unbalance is caused primarily by the relatively large electrostatic capacitance of the grounded tank relative to the capacitance of the contact parts. The voltage balance depends on the type of short circuit, whether grounded or ungrounded, as well as the spacings and capacitances of the parts involved.

It has been claimed by some that the unbalance referred to could not be disposed of in a commercial structure of the conventional type, and therefore radically different structures eliminating the metal tank have been proposed. This is not necessary, however, and the safety and ruggedness of the grounded tank still may be used, as shown by Mr. Van Sickle.

In 1929 and 1930 the general idea of using capacitance to balance that of the tank was used when the deion grids on the Plymouth Meeting 220-kv breakers of the Philadelphia Electric Company were designed with plate condensers in the upper units. Several other applications of the same principle have been since made.

The 3-cycle Boulder Dam 287-kv breakers required a more intensive application of the shunt capacitance principle, since over-all operation at this voltage made necessary complete duration of arcing of not over $1^1/_2$ cycles.

A paper in the AIEE for June 1937 by Wilcox and Leeds discussed these breakers and showed the performance well within 3 cycles on a 60-cycle basis can be expected during short circuit duty. Mr. Van Sickle's paper covers the methods of securing voltage distribution used in that design. The fact of proper distribution has been proved by several types of test:

1. Low-voltage electrostatic tests
2. High-voltage electrostatic tests
3. High-voltage dynamic tests using high-power laboratory

All 3 methods have borne out very closely the results expected from simple calculations of the electrostatic factors involved. Such calculations on a pure capacitance basis are slightly pessimistic, as the natural resistance characteristic of arcs in the interrupting devices tend to better the distribution.

Where exceedingly short times for switching are required at very high voltages, it must be conceded that some device to secure adequate distribution of voltage must be used. Recent claims for high speed at high voltages for devices which have inherently bad unbalance between breaks must be discounted as probably due to low rates of restored voltage. This will be seen if we look at figure 3 of Mr. Van Sickle's paper. Notice that in the curve for 8 breaks, the line break must handle 30 per cent of the total voltage across the pole unit, while on the other hand the last 4 breaks near ground total only 22 per cent, or less than the first single break. The tendency of the first break to re-establish an arc after current zero on a difficult high-voltage circuit is obvious.

On the other hand, figure 4 shows for 8 breaks that when proper devices for voltage balance are used, the first break handles only 16 per cent of the voltage across the pole unit, and the last 4 breaks average 10 per cent each and total 40 per cent of the pole unit voltage.

The design factors involved in very high speed, high-voltage breakers make these differences in voltage distribution a major factor in the ability of a design to handle difficult circuits, which at 230,000 volts or higher may have restored voltage rates of 4,000 to 6,000 volts per microsecond.

**C. A. Powel** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The multibreak circuit breaker is not new. Many years ago several manufacturers introduced various designs of such breakers but their performance was not strikingly better than that of ordinary 2-break breakers, in fact, generally not as good. In a paper presented to the first International Conference on High Voltage Systems in Paris in 1921, the writer pointed out that unless some means was found to reduce the total length of the arc, the volume of gas generated by a multiplicity of breaks was increased and arc interruption was made more difficult. A serious difficulty, which was not fully understood at the time, was the proper distribution, after current zero, of the voltage across the many breaks which tended to restrike and prevent extinction of the arcs. With the introduction of the "deion" grid, the arc energy and formation of gas was enormously reduced and the multibreak idea became interesting if an over-all opening time of less then 8 cycles, which had been reached with the conventional 2-break design, was required. The difficulty of proper distribution of the voltage over the various breaks, however, still remained, and how it was solved is admirably explained in Mr. Van Sickle's paper. In the great majority of cases stability is the factor which determines the selection of breaker opening time, and the conventional 8-cycle breaker economically meets most operating requirements. In some few cases, however, a shorter time of opening can be justified and it is a satisfaction to know that where such an application proves economical, a design of breaker is available which is not radically different from that used for years.

## The Ultrahigh-Speed Reclosing Expulsion Oil Circuit Breaker

**Discussion and author's closure of a paper by A. C. Schwager published in the August 1937 issue, pages 968–70, and presented for oral discussion at the development of protective equipment session of the Pacific Coast convention, Spokane, Wash., August 31, 1937.**

**W. F. Skeats** (General Electric Company, Philadelphia, Pa.): Mr. Schwager has developed a mechanism for making the complete opening and closing strokes of a 69-kv breaker within half a second. This will undoubtedly find an application in connection with interrupting devices which cannot be relied upon to clear appreciably before the end of the stroke and in cases where the shorter reclosing times which have been reported by other authors are not considered necessary. It appears, however, that this mechanism must complete its closing stroke before starting to open, so that the trip-free feature which is now applied very widely on large oil circuit breakers has been sacrificed.

In evaluating the tests which are listed, it would be interesting to know the interrupting capacity rating of the breakers tested. Without this information, it is not clear whether the tests were made on breakers of low interrupting capacity or whether the power available for testing was considerably less than the breaker rating. In the second case, while the tests no doubt establish the adequacy of the interrupting devices for the duty at which they are to be applied, it cannot be inferred without further proof that the interrupting capacity of the breaker is not modified by the short interval between interruptions.

It is noted that the duration of the second short circuit at figure 5 is approximately 14 cycles as against a little over 8 cycles for the first interruption. This is apparently due to the fact that in the second interruption was a closing-opening operation in which the breaker was delayed by the fact that the mechanism is not trip-free, but has to close all the way home before it can start to open.

**A. C. Schwager:** Mr. Skeats discusses the reclosing mechanism developed for 69-kv breakers and points out that the reclosing time of $^1/_2$ second is larger than that en-

countered on some more recently built mechanisms. The mechanism shown in figure 3 is the first motor-operated reclosing control installed in the United States and fully meets the requirements for which it was designed. It is believed that a control of this type will find application in a great many cases. However, in order to meet special requirements for still shorter reclosing times changes have been incorporated in more recent designs. These changes mainly consist of using a spring of smaller diameter, thereby reducing the moment of inertia and increasing the speed of operation. The duration of the second short circuit referred to in the third paragraph of Mr. Skeats' discussion (which in the case shown includes relay time) is thereby reduced to a value which is equal to or smaller than that obtained with any modern "trip free in any position" mechanism.

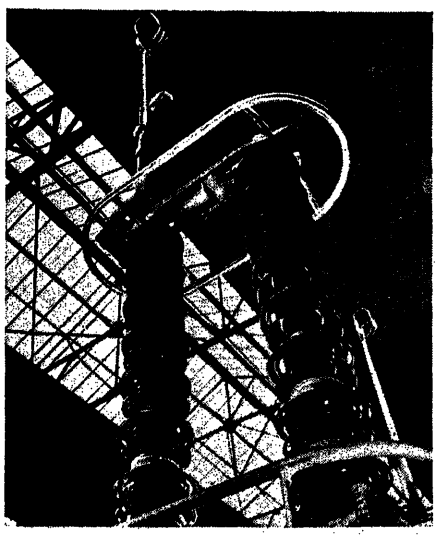
The short-circuiting tests described were performed on a 69-kv breaker which was equipped with expulsion contacts at the time of the installation of the control. The tests were not intended to be short-circuiting tests of the 1,000,000-kva breaker, but were to establish the performance of the breaker under fast reclosing service at maximum system load. The absence of carbonization and tank pressures indicate, however, that the breaker was stressed to a fraction of its full rating only.

The "trip free in any position " feature mentioned deserves a more detailed discussion. It is, of course, evident that the "electrically trip free" and "mechanically trip free" feature generally applied on breakers is retained in this mechanism. Mr. Skeats, in all probability, refers to the "trip free in any position of the closing stroke" feature.

This feature, in my opinion, has become of minor importance with the design of breakers using high-pressure contacts or butt-type contacts. Approximately one inch of travel is allowed in these breakers from the "contact touch" to the fully closed position. With the closing speeds used in present-day breakers, the blade cannot help but to go fully closed even if the breaker were tripped at the instant the contacts touch. With relays interposed it is even more impossible for these breakers not to go fully closed when closed into a short circuit. There are definite advantages in omitting the collapsible link which is normally identified with the term "trip free in any position" and which has been used on "modern" controls for the last 30 years. With its use the blade has to be accelerated by the opening spring exclusively whereas with the motor control described, the kinetic energy contained in the fast-moving spring is immediately and completely converted into opening speed.

Since modern arc-rupturing devices are dependent on operation above a definite minimum speed the use of this control gives assurance of fool-proof performance which cannot be expected of a breaker which has to be relied upon to accelerate in the part of the stroke where interruption should take place. In other words, the breaker cannot hang within the arc-rupturing devices.

It is believed that the intentional omission of the obsolete collapsible link mechanism is highly desirable from an operating standpoint alone, however, since it permits the design of such a mechanically simple and fool-proof control as described it seems to be doubly justified. Experience with this modern control will undoubtedly confirm this idea.



## A Comprehensive Method of Determining the Performance of Distance Relays

**Discussion and author's closure of a paper by J. H. Neher published in the July 1937 issue, pages 833–44, and presented for oral discussion at the development of protective equipment session of the Pacific Coast convention, Spokane, Wash., August 31, 1937.**

**L. F. Kennedy** (General Electric Company, Philadelphia, Pa.): Mr. Neher deserves the thanks of all protective engineers for the work he has put forth in preparing the formulas included in table II. I have some idea of the vast amount of time necessary for its preparation. Many are familiar with the changes of distance relay indications between 3-phase faults and phase-to-phase faults when star-connected current transformers are used. Few, however, know the indications under all the conditions covered by this paper.

I am afraid that the author's work will not be made use of by many relay engineers because of lack of time and facilities for the necessary calculations. I should like to suggest that the formulas in table II be supplemented by actual figures for an assumed typical system. Such an effort would not represent a great amount of work in addition to that already done and would certainly make the author's efforts of real value.

**C. R. Mason** (General Electric Company, Schenectady, N. Y.): Some of your best friends are those you take the longest to get acquainted with. If you should feel that Mr. Neher's paper is a reticent sort of neighbor, I suggest that you proceed carefully but studiously toward making its acquaintance. It is my feeling that it will then be numbered among your choicest possessions.

Supplementing the excellent treatments by Lewis and Tippet and by Calabrese, Mr. Neher's paper sheds new light on the subject. Perhaps I should say light at a different angle. For, in this paper the conception of impedance at an angle is skillfully handled. For example, the operating characteristic of a relay which functions according to 3 variables, such as most distance and directional relays, is very conveniently drawn to 2 dimensions without parameters to confuse the picture. Then all possible types of faults are expressed in the same manner, and conveniently tabulated. This in itself represents a creditable contribution.

This method of treatment is particularly valuable where one is confronted by the problem of determining a new shape for a relay characteristic to fit certain special requirements. The requirements can be plotted in the form of impedance at an angle and then a relay curve or portions of curves can be drawn to fit the requirements. The methods of this paper thus operate conveniently either way—to find out how a given relay will operate under prescribed conditions or to devise a relay or a combination of relays to operate in a desired manner.

If a fourth variable, time, should be involved, this can still be cared for by the use of parameters.

Mr. Neher's methods provide a very powerful analytical tool which is well worth having on your work bench.

**J. H. Neher:** I wish to thank Messrs. Kennedy and Mason for their very kind remarks about this paper. I feel obliged to point out the fact, which was displayed too inconspicuously as a footnote in the printed copy, that I am indebted to their associate, Mr. Warrington for a good deal for which they are giving me credit.

Mr. Kennedy has suggested that the formulas in table II be supplemented by actual figures for an assumed typical system. I hesitate to do this because, as I have endeavored to point out, in some cases the impedance presented to a relay under a given fault condition is only a function of the effective line impedance between the relay and the point of fault, and in other cases it is dependent upon the system set-up as well. This can be determined by inspection of table II by noting whether or not the expressions for the impedance presented to the relay involve factors dependent upon the system set-up. In cases where the effect of system capacity is manifest, any figures which might be included based on an assumed system, would apply only to the particular system set-up assumed and might lead to erroneous conclusions if one were to generalize from them.

In preparing a paper of this kind the elimination of errors in the mathematical text is difficult. On page 834 directly below equation number 3 a square root sign should appear over the numerator of the expression given in the text for the radius of the circle. In table II the factors $C$ and $C'$ have been incorrectly printed in small letters in columns 5 and 8, lines 8 and 10. Also, in the first 2 lines of the seventh column a small $z$ has been omitted in the denominators after the factor small $c$.

# AIEE Winter Convention to Feature Enlarged Program

TO PROVIDE added interest for the specialist as well as the average member, an enlarged program of 16 technical sessions and 1 general interest session has been tentatively arranged for the 1938 AIEE winter convention, which will be held in New York, N. Y., January 24–28. Sessions will be held both mornings and afternoons beginning on Monday and continuing through Thursday. Friday, the fifth day, will be devoted exclusively to inspection trips to places of interest in the city and its environs. The main social events will consist of the smoker and the dinner-dance, which will be held in the evenings. In view of the popularity of last year's cruise, another post-convention cruise to Bermuda will be arranged by Leon V. Arnold. More information regarding these features will be announced in the January issue.

TECHNICAL SESSIONS

Of the 16 technical sessions tentatively arranged, 5 sessions are symposia. The symposium on modern electric vehicles will be held in both the morning and afternoon of the same day with interim for luncheon; the papers will deal with modern developments and experience with electric vehicles used in urban transportation. Similarly, two electronics symposia will be held: The first will treat the speed control of motors, and operating experience; the second, electronic applications and the slide-

## Tentative Technical Program

**In this program page references are given for papers that have been or will be published in ELECTRICAL ENGINEERING up to and including January 1938.**

### Communication

COUPLING BETWEEN PARALLEL EARTH-RETURN CIRCUITS UNDER D-C TRANSIENT CONDITIONS, K. E. Gould, Bell Telephone Laboratories, Inc.
September issue, pages 1159–64

*PRINTING TELEGRAPH OPERATION OF WAY WIRES, G. S. Vernam, Postal Telegraph-Cable Company.

*ELECTRICAL REMOTE CONTROL ACCOUNTING, L. F. Woodruff, Massachusetts Institute of Technology.

A NEW SINGLE-CHANNEL CARRIER TELEPHONE SYSTEM, H. J. Fisher, M. L. Almquist, and R. H. Mills, Bell Telephone Laboratories, Inc.
Scheduled for January issue

### Symposium on Modern Electric Vehicles

APPLICATION OF MODERN ELECTRIC VEHICLES TO URBAN TRANSPORTATION, C. M. Davis, General Electric Company. Scheduled for January issue

ELECTRICAL EQUIPMENT FOR MODERN URBAN SURFACE TRANSIT, S. B. Cooper, Westinghouse Electric & Manufacturing Company.
Scheduled for January issue

*GENERAL FEATURES OF THE P.C.C. CAR, C. F. Hirshfeld, Transit Research Corporation.

*OPERATING EXPERIENCE WITH P.C.C. CAR, Thomas Fitzgerald, Pittsburgh Railways Company.

### Symposium on a New Carrier Telephone System for Toll Cable

Introductory Address: BROAD-BAND WIRE TRANSMISSION SYSTEMS, H. A. Affel, Bell Telephone Laboratories, Inc.

*A CARRIER TELEPHONE SYSTEM FOR TOLL CABLES, C. W. Green and E. I. Green, Bell Telephone Laboratories, Inc.

*CABLE CARRIER TELEPHONE TERMINALS, R. W. Chesnut, L. M. Ilgenfritz and A. Kenner, Bell Telephone Laboratories, Inc.

* Subject to approval for presentation, preprints of these papers will be made available. If ordered by mail, price 10¢ per copy. If purchased at headquarters, price 5¢ per copy.

*CRYSTAL CHANNEL FILTERS FOR THE CABLE CARRIER SYSTEM, C. E. Lane, Bell Telephone Laboratories, Inc.

*CROSS TALK AND NOISE FEATURES OF THE CABLE CARRIER SYSTEM, M. A. Weaver, R. S. Tucker, and P. S. Darnell, Bell Telephone Laboratories, Inc.

### Symposium on Modern Electric Vehicles—Continued

*MODERN CITY TRANSPORTATION, E. J. McIlraith, Chicago Surface Lines.

MODERN TROLLEY-COACH OPERATION, Edward Dana, Boston Elevated Railway.
December issue, pages 1461–63

MODERN TROLLEY-COACH OPERATION, J. H. Polhemus, Portland Electric Power Company.
December issue, pages 1483–86

*OPERATING EXPERIENCE WITH GAS-ELECTRIC AND DIESEL-ELECTRIC BUSSES, R. H. Stier, Philadelphia Rapid Transit Company.

*EXPERIENCE WITH DIESEL-ELECTRIC BUSSES AND ALL-SERVICE VEHICLES, M. R. Boylan, Public Service Coordinated Transport.

### Lightning Protection

CHARACTERISTICS OF THE NEW STATION-TYPE AUTOVALVE LIGHTNING ARRESTER, W. G. Roman, Westinghouse Electric & Manufacturing Company.
July issue, pages 819–22

*DISCHARGE CURRENTS IN DISTRIBUTION ARRESTERS—PART II, K. B. McEachron and W. A. McMorris, General Electric Company.

*DISTRIBUTION TRANSFORMER LIGHTNING PROTECTION PRACTICE, L. G. Smith, Consolidated Gas, Electric Light and Power Company.

SOME ENGINEERING FEATURES OF PETERSEN COILS AND THEIR APPLICATION, E. M. Hunter, General Electric Company.
Scheduled for January issue

*TEST AND OPERATION OF PETERSEN COIL ON 100-KV SYSTEM OF PUBLIC SERVICE COMPANY OF COLORADO, W. D. Hardaway, Public Service Company of Colorado, and W. W. Lewis, General Electric Company.

### Symposium on Electronics—I

*ELECTRONIC SPEED CONTROL OF MOTORS, E. F. W. Alexanderson, General Electric Company, C. H. Willis, Princeton University, and M. A. Edwards, General Electric Company.

OPERATING EXPERIENCE WITH THE THYRATRON MOTOR, A. H. Beiler, American Gas and Electric Company. Scheduled for January issue

*PHANOTRON RECTIFIERS AS A DIRECT CURRENT SUPPLY FOR ELEVATOR MOTORS, C. C. Clymer and R. G. Lorraine, General Electric Company.

*THYRATRON CONTROL OF DIRECT CURRENT MOTORS, G. W. Garman, General Electric Company.

### Relays and Reactors

A SYSTEM OUT OF STEP AND ITS RELAY REQUIREMENTS, L. C. Crichton, Westinghouse Electric & Manufacturing Company.
October issue, pages 1261–67

A HIGH-SPEED DISTANCE-TYPE CARRIER PILOT RELAY SYSTEM, E. L. Harder, B. E. Lenehan, and S. L. Goldsborough, Westinghouse Electric & Manufacturing Company.
Scheduled for January issue

*THE APPLICATION AND PERFORMANCE OF CARRIER CURRENT RELAYING, Philip Sporn and C. A. Muller, American Gas and Electric Company.

TEMPERATURE LIMITS FOR SHORT-TIME OVERLOADS FOR OIL-INSULATED NEUTRAL GROUNDING REACTORS AND TRANSFORMERS, V. M. Montsinger, General Electric Company.
Scheduled for January issue

*HARMONIC CURRENT RESTRAINED RELAYS FOR DIFFERENTIAL PROTECTION, L. F. Kennedy and C. D. Hayward, General Electric Company.

*SOME SCHEMES OF CURRENT-LIMITING REACTOR APPLICATIONS, F. H. Kierstead, General Electric Company.

back voltmeter, theater lighting, welding, and a new type of vacuum seal. The fifth symposium will deal with a new carrier telephone system for toll cable. Also in the communication field, there will be a general communication session and another session on the subject of television and broad band transmission. The remainder of the program is comprised of sessions on the subjects of lightning protection, relays and reactors, instruments and measurements, electric welding, basic sciences, power transmission, cables and research, and two sessions on electrical machinery. For the general session arrangements are being made to obtain a prominent speaker on a subject of broad interest to the engineering profession.

### Technical Conferences

During the convention, technical conferences will be held on the subjects of education, field problems, network analysis and synthesis, electrical units, sound and vibration. The technical conferences are intended to afford opportunity for groups of specialists to meet and discuss subjects informally, no provision being made for the publication of the papers or the discussions in the TRANSACTIONS.

### Rules on Presenting and Discussing Papers

At some of the technical sessions, a few papers may be presented only by title. This will permit the devotion of more time to discussion. At other sessions, papers will be presented in abstract, ten minutes being allowed for each paper unless otherwise arranged, or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion. Authors will be notified officially in each case about one month in advance.

Any member is free to discuss any paper when the meeting is opened for general discussion. Usually five minutes is allowed to each discusser for the discussion of a single paper or of several papers on the same general subject. When a member signifies his desire to discuss several papers not dealing with the same general subject, he may be permitted to have a somewhat longer time.

It is preferable that a member who wishes to discuss a paper give his name in advance to the presiding officer of the session at which the paper is to be presented. Each discusser should step to the front of the room and announce, so that all may hear, his name and professional affiliations. Three typewritten copies of discussion prepared in advance should be left with the presiding officer.

Other discussions to be considered for publication must be submitted, typed double spaced, in triplicate to C. S. Rich, secretary, technical program committee, AIEE headquarters, 33 West 39th St., New York, N. Y., on or before February 11, 1938. Discussion received after this date will not be accepted.

The personnel of the 1938 winter convention committee is as follows: T. F. Barton, *chairman*, C. R. Beardsley, O. B. Blackwell, G. E. Dean, A. F. Dixon, E. E. Dorting, H. S. Osborne, C. S. Purnell, George Sutherland, and F. P. West.

# Tentative Technical Program—Continued

## Symposium on Electronics—II

*SHARP CUT-OFF IN VACUUM TUBES, WITH APPLICATIONS TO THE SLIDE-BACK VOLTMETER, C. B. Aiken, Purdue University, and L. C. Birdsall, Glencoe, Ill.

*THYRATRON REACTOR LIGHTING CONTROL, E. D. Schneider, General Electric Company.

*AN ELECTRONIC ARC-LENGTH MONITOR, Walther Richter, A. O. Smith Corporation.

*A NEW TYPE VACUUM SEAL, W. E. Bahls, Westinghouse Electric & Manufacturing Company.

## Instruments and Measurements

*A NEW ALTERNATING-CURRENT NETWORK ANALYZER, H. P. Kuehni and R. G. Lorraine, General Electric Company.

*A STABILIZED AMPLIFIER FOR MEASUREMENT PURPOSES, H. A. Thompson, General Electric Company.

ELECTRICAL STUDIES OF LIVING TISSUE—II—CORRELATION BETWEEN TISSUE RESPONSE AND VOLTAGE DISTRIBUTION, A. G. Conrad, H. W. Haggard, and B. R. Teare, Yale University.
Scheduled for January issue

A NEW CORRELATION OF SPHERE GAP DATA, D. W. Ver Planck, Yale University.
Scheduled for January issue

## Electric Welding

RECENT ADVANCES IN RESISTANCE WELDING, AIEE Resistance Welding Subcommittee, C. L. Pfeiffer, chairman. Scheduled for January issue

MECHANICAL HIGH-SPEED RESISTANCE-WELDER CONTROL, F. H. Roby, Square D Company.
September issue, pages 1145–48

*INTERPRETATION OF OSCILLOGRAMS OF ARC-WELDING GENERATORS IN TERMS OF WELDING PERFORMANCE, K. L. Hansen, Harnischfeger Corporation.

*THE RATING OF RESISTANCE-WELDING TRANSFORMERS, C. E. Heitman, Edward G. Budd Manufacturing Company.

## Basic Sciences

MATRICES IN ENGINEERING, L. A. Pipes, The Rice Institute. September issue, pages 1177–90

*RESONANT NONLINEAR CONTROL CIRCUITS, W. T. Thomson, Alameda, Calif.

*SUBHARMONICS IN CIRCUITS CONTAINING IRON, I. A. Travis and C. N. Weygandt, University of Pennsylvania.

*THE PROPERTIES OF THREE-PHASE SYSTEMS DEDUCED WITH THE AID OF MATRICES, M. B. Reed, The University of Texas.

*CRITICAL CONDITIONS IN FERRO-RESONANCE, P. H. Odessey and Ernst Weber, The Polytechnic Institute of Brooklyn.

## Power Transmission

*TRANSMISSION LINE TRANSIENTS IN MOTION PICTURES, L. F. Woodruff, Massachusetts Institute of Technology.

*LIGHTNING STRENGTH OF WOOD IN TRANSMISSION STRUCTURES, Philip Sporn, American Gas and Electric Company, and J. T. Lusignan, Ohio Brass Company.

*RECOVERY-VOLTAGE CHARACTERISTICS OF TYPICAL TRANSMISSION SYSTEMS AND RELATION TO PROTECTOR-TUBE APPLICATION, R. D. Evans and A. C. Monteith, Westinghouse Electric & Manufacturing Company.

SWITCHING SURGES WITH TRANSFORMER LOAD-RATIO CONTROL CONTACTORS, L. F. Blume and L. V. Bewley, General Electric Company.
December issue, pages 1464–75.

*SAFETY FEATURES FOR THE JOINT USE OF WOOD POLES CARRYING COMMUNICATION CIRCUITS AND POWER DISTRIBUTION CIRCUITS ABOVE 5,000 VOLTS, J. O'R. Coleman, Edison Electric Institute, and A. H. Schirmer, Bell Telephone Laboratories, Inc.

## Electrical Machinery—I

CO-ORDINATION OF POWER TRANSFORMERS FOR STEEP-FRONT IMPULSE WAVES, V. M. Montsinger, General Electric Company.

CORONA VOLTAGES OF TYPICAL TRANSFORMER INSULATIONS UNDER OIL, F. J. Vogel, Westinghouse Electric & Manufacturing Company.
Scheduled for January issue

A FORMULA FOR THE REACTANCE OF THE INTERLEAVED COMPONENT, H. B. Dwight and L. S Dzung, Massachusetts Institute of Technology
November issue, pages 1368–71

*STABILITY CHARACTERISTICS OF TURBINE GENERATORS, C. Concordia, S. B. Crary, and J. M. Lyons, General Electric Company.

## Cables and Research

OIL OXIDATION IN IMPREGNATED PAPER, J. B. Whitehead, The Johns Hopkins University, and T. B. Jones, Bell Telephone Laboratories, Inc.
December issue, pages 1492–1502

*MECHANICAL UNIFORMITY OF PAPER-INSULATED CABLE, K. S. Wyatt, D. L. Smart, and J. M. Reynar, The Detroit Edison Company.

*THE CURRENT-CARRYING CAPACITY OF RUBBER-INSULATED CONDUCTORS, S. J. Rosch, Anaconda Wire & Cable Company.

SHORT-CIRCUIT PROTECTION OF DISTRIBUTION NETWORKS BY THE USE OF LIMITERS, C. P. Xenis, Consolidated Edison Company of New York, Inc.
September issue, pages 1191–96

## Television

Address:. CURRENT FIELD WORK IN TELEVISION Ralph R. Beal, Radio Corporation of America.

Address: NEW BROAD-BAND TELEPHONE SYSTEM H. A. Affel, Bell Telephone Laboratories, Inc.

## Electrical Machinery—II

STRAY-LOAD LOSSES OF D-C MACHINES, E. W. Schilling, Michigan College of Mining and Technology, and R. W. Koopman, University of Kansas.
December issue, pages 1487–91

D-C MACHINE STRAY-LOAD-LOSS TESTS, Victor Siegfried, Worcester Polytechnic Institute.
October issue, pages 1285–89

UNSYMMETRICAL SHORT-CIRCUITS ON WATER-WHEEL GENERATORS UNDER CAPACITIVE LOADING, C. F. Wagner, Westinghouse Electric & Manufacturing Company. November issue, pages 1385–95

ALTERNATOR SHORT-CIRCUIT CURRENTS UNDER UNSYMMETRICAL TERMINAL CONDITIONS, A. R. Miller and W. S. Weil, Jr., Lehigh University.
October issue, pages 1268–76

# AIEE Board of Directors Meets at Institute Headquarters

THE regular meeting of the board of directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on October 28, 1937.

There were present: *President*—W. H. Harrison, New York, N. Y. *Past-Presidents*—A. M. MacCutcheon, Cleveland, Ohio; J. B. Whitehead, Baltimore, Md. *Vice-Presidents*—O. B. Blackwell, New York, N. Y.; C. Francis Harding, Lafayette, Ind.; M. J. McHenry, Toronto, Ont.; I. Melville Stein, Philadelphia, Pa.; A. C. Stevens, Schenectady, N. Y.; Edwin D. Wood, Louisville, Ky. *Directors*—C. R. Beardsley, Brooklyn, N. Y.; V. Bush, Cambridge, Mass.; N. E. Funk, Philadelphia, Pa.; F. Ellis Johnson, Columbia, Mo.; C. R. Jones, New York, N. Y.; W. B. Kouwenhoven, Baltimore, Md.; F. H. Lane, Chicago, Ill.; K. B. McEachron, Pittsfield, Mass.; C. A. Powel, East Pittsburgh, Pa.; R. W. Sorensen, Pasadena, Calif. *National Treasurer*—W. I. Slichter, New York, N. Y. *National Secretary*—H. H. Henline, New York, N. Y. Present by invitation: V. M. Montsinger, chairman, standards committee.

Minutes of the meeting of the board of directors held August 3, 1937, were approved.

Representatives and alternates of the Institute on other organizations were appointed as follows:

**United Engineering Trustees, Inc.**—for 4-year term beginning in October 1937: F. M. Farmer.

**American Engineering Council Assembly**—for calendar year 1938: C. O. Bickelhaupt, chairman, AIEE delegation; C. Francis Harding; William McClellan; C. E. Stephens; H. H. Henline, alternate. President W. H. Harrison is the fifth representative of the Institute, for the term August 1, 1937, to August 1, 1938.

**Standards Council, ASA**—for 3-year term beginning January 1, 1938: E. L. Moreland. Alternates for calendar year 1938: R. E. Hellmund; H. H. Henline; H. S. Osborne.

**Engineers' Council for Professional Development**—for 3-year term beginning in October 1937: F. Ellis Johnson.

The following were appointed for the year beginning August 1, 1937:

**Committee of Apparatus Makers and Users, National Research Council:** L. F. Adams.

**Electrical Standards Committee, ASA** (and, *ex-officio*, United States National Committee of the International Electrotechnical Commission): A. M. MacCutcheon; V. M. Montsinger; H. S. Osborne. Alternates: H. E. Farrer; R. E. Hellmund; E. L. Moreland.

**Committee on Heat Transmission, National Research Council:** T. S. Taylor.

**Committee on Low Voltage Hazards, ASSE Engineering Section, National Safety Council:** F. V. Magalhaes.

**Electrical Committee, National Fire Protection Association:** F. V. Magalhaes.

**National Fire Waste Council:** Wills Maclachlan, H. S. Warren.

It was decided to discontinue the appointment of representatives upon the following bodies, reports having been received of inactivity of the organization or of no further need for Institute representation: American Marine Standards Committee, and the Radio Advisory Committee of the National Bureau of Standards.

The following actions of the executive committee under date of September 20, 1937, were reported and confirmed: 4 applicants transferred to grade of Fellow; 20 applicants transferred and 7 elected to the grade of Member; 57 applicants elected to the grade of Associate; 32 Students enrolled.

Reports were presented and approved of meetings of the board of examiners held on September 16 and October 14, 1937. Upon recommendation of the board of examiners, the following actions were taken: 13 applicants were elected and one applicant was reinstated to the grade of Member; 50 applicants were elected to the grade of Associate; 843 Students were enrolled.

Monthly disbursements were reported by the finance committee and approved by the board of directors as follows: August, $24,804.67; September, $19,296.69; October, $35,234.32.

Upon the recommendation of the finance committee, the board authorized the transfer of the sum of $7,500 from last year's surplus in general funds to the reserve capital fund, and its investment in General Motors Acceptance Corporation bonds; and appropriated from last year's surplus the sum of $1,500 for the Institute's share of the cost of new book stacks for the Engineering Societies Library.

A budget, which had been prepared by the finance committee, was adopted for the appropriation year beginning October 1, 1937. Detailed budget information may be found on other pages in this issue.

The budget included provision for the reestablishment of cash prizes of $100 each for the national prize for initial paper and the national prize for Branch paper and of $25 each for the District prizes for initial papers, as recommended by the committee on award of Institute prizes if complete restoration this year of all cash prizes should not be considered practicable; also for the continuation of the cash prizes of $25 each for the District prizes for Branch papers.

A revised publication policy was adopted, as recommended by the publication committee. (Announcement was made in ELECTRICAL ENGINEERING for November 1937, page 1409.)

The chairman of the publication committee reported on the sales of the "Lightning Reference Book," which had been prepared by a subcommittee of the committee on power transmission and distribution and published by the AIEE. The sales indicate that the project will be self-sustaining.

Upon recommendation of the Section and District officers concerned, the board approved the dates, August 9–12, 1938, for the Pacific Coast convention to be held at Portland, Oregon.

Sections 81 and 68 of the by-laws were amended as follows, to bring them in accord with action of the board of directors, in June 1937, in approving certain recommendations of the committee on safety codes, which included a change in name of the committee to "committee on safety":

Section 81 changed to read:

**Sec. 81. The committee on safety shall consist of 15 members, and shall consider and investigate matters relating to the protection of persons and property against hazard due to or resultant upon the presence of electricity or the use of electrical apparatus, material, and appliances, and shall report to the board of directors such recommendations thereon as it shall deem desirable for action by the Institute. To this end it shall encourage and co-ordinate safety considerations by other Institute committees in their respective fields, and with the approval of the board of directors, may arrange for co-operative relations with other bodies in the consideration of electrical hazard.**

The first sentence of section 68 changed to read:

**Sec. 68. The technical program committee shall consist of 9 members; and the chairman of each technical committee, the chairman of the committee on co-ordination of Institute activities, and the chairman of the committee on safety, *ex-officio*.**

The following board members were selected to serve as members of the national nominating committee for the year 1937–1938: C. R. Beardsley, O. B. Blackwell, V. Bush, R. W. Sorensen, and A. C. Stevens. Mr. C. R. Jones was designated an alternate.

Upon recommendation of the standards committee, the board approved a revised edition of American Standard for Power Operated Radio Receiving Appliances, which had been submitted for approval by the Underwriters' Laboratories, proprietary sponsor for the project.

It was reported that, at the annual meeting of The Engineering Foundation on October 14, the budget for the fiscal year October 1, 1937, to September 30, 1938, was adopted, and it contained appropriations for research projects recommended by the AIEE, namely, stability of impregnated-paper insulation, and electric shock.

Other matters were discussed, reference to which may be found in this or future issues of ELECTRICAL ENGINEERING.

# Tulsa Section Holds Organization Meeting

Eighty-one members and guests attended the organization meeting of the AIEE Tulsa (Okla.) Section, October 18, 1937, which was authorized by the Institute's board of directors June 24. This is the Institute's 64th Section, the 63d having been organized recently at Wichita, Kans. Officers elected to take office immediately are: R. K. Lane (M'37) Public Service Company of Oklahoma, Tulsa, chairman; A. Naeter (A'23, M'30) Oklahoma Agricultural and Mechanical College, Stillwater, vice-chairman; and D. J. Tuepker (A'37) Public Service Company of Oklahoma, Tulsa, secretary.

H. L. Andrews (A'16, M'26) vice-president, General Electric Company, New York, N. Y., spoke on "Modern Transportation," a subject of wide interest as indicated by the discussion which followed.

**Electricity Production Record.** Production of electricity for public use in the United States reached a new high of 118,809,000,000 kilowatt-hours in the 12-month period ending September 30, 1937, the Federal Power Commission has reported. Total production in September was 9,985,000,000 kilowatt-hours as compared with 10,378,-

000,000 in August, which, on a comparable basis, is an increase of 7.2 per cent over September 1936. Average daily production in September was 332,833,000 kilowatt-hours, 0.2 per cent less than the average daily production in August. Production by water power in September was 32 per cent of the total. Considerable increases have been recorded every month this year over the same months in 1936. Electric-utility power plants consumed 4,030,059 net tons of coal in September 1937. Of this amount, 3,872,264 tons were bituminous coal and 157,795 tons were anthracite, decreases of 4.0 per cent and 1.6 per cent, respectively, when compared with consumption in the preceding month.

## John Fritz Medal for 1937 Awarded to P. D. Merica

Paul Dyer Merica, director of research of the International Nickel Company and vice-president of the International Nickel Company of Canada, has been awarded the 1938 John Fritz Gold Medal, highest of American engineering honors, for "important contributions to the development of alloys for industrial uses." The award is made annually for notable scientific or industrial achievement by a board composed of representatives of the 4 national engineering societies of civil, mining and metallurgical, mechanical, and electrical engineers.

Doctor Merica's extensive research in theoretical and practical metallurgy has increased scientific knowledge in both ferrous and nonferrous fields, the citation of the board points out. "He has contributed generously to the science of metals, his work having covered the magnetic mechanical properties of steel; railway materials; failure of brass; the constitution, manufacture, and application of light alloys of aluminum; heat treatment of cast aluminum alloys; the precipitation theory of hardening of metals; and nickel and nickel alloys," it is declared.

Doctor Merica was born at Warsaw, Ind., on March 17, 1889. He studied from 1904 to 1907 at De Pauw University, which in 1934 conferred upon him the degree of doctor of science. In 1909 he received the bachelor of arts degree from the University of Wisconsin, and in 1914 the degree of doctor of philosophy from the University of Berlin. Following 5 years of work as research physicist in the United States Bureau of Standards, Doctor Merica in 1919 became director of research of the International Nickel Company. His home is at Millwood, N. Y.

He is a fellow of the American Association for the Advancement of Science, and a member of the American Chemical Society, the Electrochemical Society, the American Society for Testing Materials, the American Physical Society, the American Institute of Mining and Metallurgical Engineers, the American Institute of Civil Engineers, the Washington Academy of Sciences, the Institute of Metals, the Iron and Steel Institute, the Canadian Institute of Mining and Metallurgy, and Deutsche Gesellschaft für Metallkunde. He is the author of many articles and monographs in scientific and technical publications, and in 1929 received the James Douglas Medal.

Representatives of the AIEE on the board of award were J. B. Whitehead (A'00, F'12, past-president, Life Member), A. W. Berresford (A'94, F'14, past-president, member for life), and A. M. MacCutcheon (A'12, F'26, past-president).

## Noble Prize Awarded to Institute Member

For his paper "Properties of Saturants for Paper-Insulated Cables," G. M. L. Sommerman (A'31, M'37) research engineer, American Steel and Wire Company, Worcester, Mass., has been awarded the Alfred Noble prize for 1937. This paper was published in the May 1937 issue of ELECTRICAL ENGINEERING, pages 566–76, and was presented for discussion at the AIEE 1937 summer convention held June 21–25 at Milwaukee, Wis. A biographical sketch of the recipient is included in the "Personal Items" section of this issue. Formal presentation of the award will take place at the AIEE 1938 winter convention to be held January 24–28 in New York, N. Y.

The Alfred Noble Prize was instituted in 1929 in honor of Alfred Noble, past-president of the American Society of Civil Engineers and the Western Society of Engineers, and consists of a $500 cash award and an engraved certificate. The award is made to a member of any grade of either the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, or the Western Society of Engineers, for a technical paper of particular merit accepted by the publication committee of any of the foregoing societies for publication, in whole or in abstract, in any of their respective technical publications, provided the author, at the time the paper is accepted in practically its final form is not over 30 years of age. The recipient of the prize is selected by a committee of five members, consisting of one representative of each society, the award being based upon papers published by the societies within the 12 months preceding July 15 of each year. The first prize was awarded in 1931.

This is the third time that a member of the AIEE has been so honored, the 1932 award having gone to F. M. Starr (A'30, M'37) and the 1936 award to Abe Tilles (A'30, M'36).

## A T & T Commemorates Works of G. A. Campbell

A volume entitled "Collected Papers of George Ashley Campbell" has just been privately printed by the American Telephone and Telegraph Company "in appreciation of Doctor Campbell's long and distinguished service, and of his fundamental contributions to the development of electrical communication." Commemorating Doctor Campbell's brilliant services to telephony, this 548-page (seven- by ten-inch) cloth-bound volume also marks his retirement from active service in the Bell System (*EE Jan. '36 p. 122*). In addition to three early memoranda on loading, the full text of some 21 of his noteworthy contributions to technical literature on communication over a period of more than 30 years are included.

In a foreword to the volume, Doctor Vannevar Bush (A'15, F'24) vice-president and dean of engineering of Massachusetts Institute of Technology, says of Doctor Campbell: "...he stands out as the one to whom the telephone art owes the realization of the loaded line, the electrical filter, and the facile treatment of the transients which pulsate in its network, and as a modest, generous character who by his very nature has inspired others to broaden into a highway the trail which he brilliantly blazed into the vast reaches of science and engineering."

ELECTRICAL ENGINEERING appreciates being authorized to state that requests for copies of this commemorative volume will be entertained by the American Telephone and Telegraph Company, 195 Broadway, New York, N. Y., as long as the rather limited edition lasts.

**Scholarship Available.** The Elizabeth Clay Howald scholarship, which carries a stipend of $3,000 payable in 12 monthly installments, was endowed by the late Ferdinand Howald, an alumnus of The Ohio State University. Any person who has shown marked ability in some field of study and has in progress work, the results of which promise to constitute important additions to knowledge, shall be deemed eligible to appointment for this scholarship. The scholar will be expected to devote his time uninterruptedly to the pursuit of his investigation. If the scholar never has had any connection with The Ohio State University, he must carry on his investigations there; otherwise investigations may be carried on elsewhere. Applications must be filed with the dean of the graduate school of The Ohio State University, Columbus, before March 1, 1938. The appointment will be made on April 1, and the time of appointment will begin July 1.

### Future AIEE Meetings

**Winter Convention**
New York, N. Y., January 24–28, 1938

**North Eastern District Meeting**
Pittsfield, Mass., May 1938

**Summer Convention**
Washington, D. C., June 20–24, 1938

**Pacific Coast Convention**
Portland, Ore., August 9–12, 1938

**Southern District Meeting**
Miami, Fla., November 1938

# National Research Council Continues Discussion of Insulation at New York Meeting

THE tenth annual meeting of the National Research Council's committee on electrical insulation of the division of engineering and industrial research attracted 144 registered guests and members of the committee for a two-day program devoted to the subject of dielectric research, November 4–5, at the Consolidated Edison Company building, New York, N. Y. Devoted to the interchange of information relative to many phases of dielectric research, this annual meeting, as usual, was notable in its unbiased attention to both the theoretical and practical aspects of the subject. The first technical session, devoted to the chemistry and physics of insulation, indicated clearly the increasing participation of the chemist and the physicist and the importance of their contributions in the solution of problems vitally important to both the manufacturer and user of electrical equipment. The committee, realizing the importance of co-ordination of the efforts of the chemist, physicist, and electrical engineer, is effectively contributing to many important advances by providing for the frank presentation of new problems and free, noncommercial discussions of products, manufacturing methods, and operating difficulties.

Representing the Consolidated Edison Company as official host, Doctor John C. Parker (A'04, F'12) vice-president of the company, delivered an address of welcome, encouraging the committee in the conduct of its work, and outlining what he termed the "selfish" interest of the electric power company in the work being carried on by the committee. Co-founder of the committee and continuing chairman, Doctor J. B. Whitehead, dean of the school of engineering of The Johns Hopkins University and past-president of the AIEE (1933–34), presided at the 3 technical sessions. W. F. Davidson (A'14, F'26), secretary of the committee, was chairman of the local committee on arrangements.

Among other features of the program were several informal group meetings for the discussion and outlining of special problems; the annual dinner meeting held Thursday evening at the Hotel Gramercy Park; a luncheon Friday noon, tendered by the Consolidated Edison Company; and several inspection trips to important plants and research laboratories located in the metropolitan area.

### Atom Physics in Insulation Research

At the Thursday dinner meeting, a motion picture "Electrifying New York" was presented by the Consolidated Edison Company, and Professor A. von Hippel (M'37) Massachusetts Institute of Technology, delivered a lecture "What Can Atom Physics Contribute to Insulation Research?" Professor von Hippel's lecture revealed the importance of some of the fundamental investigations of the theoretical physicist in the domain of insulation research, and served to emphasize the value of a closer understanding between the physicist and others working in that field.

At the conclusion of the technical sessions a resolution to record in the minutes of the meeting the death (ELECTRICAL ENGINEERING for November 1937, pages 1427–28) of Henry Wright Fisher (A'95, M'01, F'12) former consulting engineer for the General Cable Corporation, and one of the pioneer cable engineers in the United States, was introduced by William A. Del Mar (A'06, M'20) and adopted unanimously by the committee.

### Full Technical Program

Characterized throughout by spontaneous enthusiasm, the 3 technical sessions included a total of 21 papers, representing the efforts of 28 authors, and related discussions. Both the presentation of the papers and their discussions were entirely informal. For those readers interested in pursuing some of the subjects further, a complete list of titles and authors is given here. Although the committee expects that many of these papers will be published in various technical journals, so far only Doctor Whitehead's annual report and a paper by Doctors Whitehead and T. B. Jones have been published in ELECTRICAL ENGINEERING. Some few of the papers presented were extensions or continuations of papers presented at the meeting of the subcommittee on chemistry of the committee on insulation held recently at Rochester, N. Y., and reported in the November 1937 issue, page 1420. Others represented continuations of studies reported at previous meetings.

#### First Technical Session—Chemistry and Physics

RECENT PROGRESS IN DIELECTRIC RESEARCH (Annual Report of Chairman), J. B. Whitehead (A'00, F'12, past-president), The Johns Hopkins University, Baltimore, Md. [*November 1937 issue, pages 1346–52.*]

ELECTRICAL AND CHEMICAL STUDIES OF OIL OXIDATION, J. C. Balsbaugh (A'23, M'25), R. G. Larsen, and J. L. Oncley, Massachusetts Institute of Technology, Cambridge.

A continuation of a paper presented by one of the authors at the Rochester meeting of the subcommittee on chemistry, this paper presents relations between oxidation stability, acid formation, power factor, colloidal content, Grignard test, oil source, and refining methods. Many phenomena of the chemical and electrical aspects of this problem are still without any satisfactory explanation.

THE DIELECTRIC BEHAVIOR OF POLYMERIC MOLECULES IN DILUTE SOLUTION, J. W. Williams, University of Wisconsin, Madison.

Admittedly a highly theoretical approach of the chemist to dielectric theory, this progress report of work being done at the University of Wisconsin contributes to the general theory by a discussion of polymeric substances of high molecular weight, and shows evidence of dielectric polarization of such substances, principally in dilute solutions.

SOME RECENT STUDIES OF DIELECTRIC BEHAVIOR AND MOLECULAR ROTATION IN SOLIDS, C. P. Smyth, Princeton University, Princeton, N. J.

A correlation of dipole rotation in long-chain molecules with molecular size and with the dielectric constant of the material. This progress report of chemical research at Princeton University shows that solids consist of rod-like molecules with perpendicular axes; increased temperature causes rotation (change from the alpha to the beta form of the substance) and change of dielectric constant. For most substances the dipole moment is independent of frequency. "Small molecules,

## Membership—

Mr. Institute Member:

The advantages of membership in the Institute have been emphasized in several excellent papers in ELECTRICAL ENGINEERING. The steady progress of the Institute is material testimony of its value. The services and opportunities it affords are numerous and varied. Some are attracted by its tangible benefits and direct services. Others are more interested in its general activities and opportunities for technical association and advancement of the electrical engineering profession.

You no doubt had definite reasons for joining the Institute. Why not tell one of your nonmember associates what they were and which of its services and opportunities you have found most valuable? You may give him an idea or viewpoint he has not previously considered which will induce him to join, and thereby receive the benefits he rightfully deserves as one connected with a branch of the electrical industry.

M. W. Smith

Vice-Chairman, District No. 2
National Membership Committee

because of their greater symmetry, are more likely to rotate in a crystal than are large molecules, but a large number of the latter have been found to give a high dielectric constant to the solid by their rotation."

DIELECTRIC PROPERTIES OF CHLORINATED NAPHTHALENES, W. A. Yager, Bell Telephone Laboratories, Incorporated, New York, N. Y.

Investigation of the dielectric behavior of a commercial polar compound, a chlorine derivative of naphthalene.

ABSORPTION OF WATER BY PAPER AT HIGH TEMPERATURES, C. C. Houtz and D. A. McLean, Bell Telephone Laboratories, Incorporated, New York, N. Y.

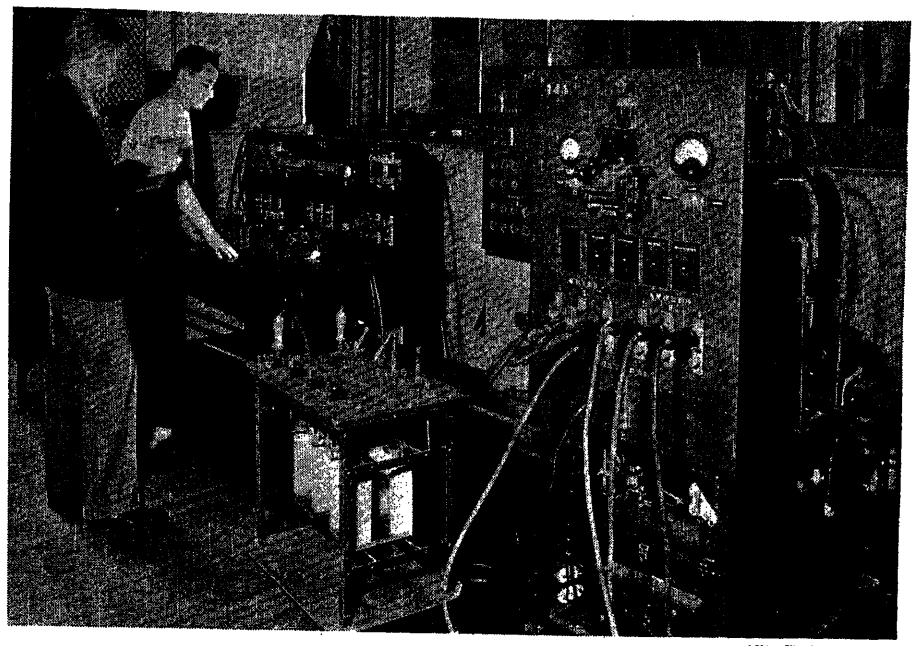
Deals with the adsorption of water by insulating paper, instead of absorption indicated by the title. Aimed toward a better understanding of the fundamental nature of paper structure, the researches described produced adsorption data for various types of paper at various water-vapor pressures.

FURTHER STUDIES OF DETERIORATION IN INSULATING OILS, R. N. Evans, Consolidated Edison Company of New York, Inc., New York, N. Y.

Describing the methods of analysis of insulation deterioration as divisible into 3 classes (1) water evolution, (2) gas evolution and (3) miscellaneous, including electrical tests, this paper presents the results of studies based upon the second method, for predicting and analyzing cable failures caused by deterioration.

Second Technical Session—
Materials and Measurements

THE EFFECT OF FILLERS ON THE ELECTRICAL PROPERTIES OF RUBBER-SULPHUR COMPOUNDS, A. H. Scott, National Bureau of Standards, Washington, D. C.



In a continuation of previous studies undertaken by the National Bureau of Standards, methods of improving the preparation of specimens and of testing have been described. "The study of the effect of fillers on the electrical properties of rubber has so far been concerned only with spherulized "kaolin" (kaolin in the form of tiny spheres). With no kaolin the power factor was 0.0026 and the dielectric constant was 2.61. With 26.5 per cent of kaolin (by volume), the power factor was 0.0047 and the dielectric constant was 3.23. The d-c conductivity did not appear to be affected by kaolin. The dielectric constant decreased linearly with the logarithm of frequency and the power factor passed through a minimum as the frequency was increased."

RUBBER AS A DIELECTRIC, A. R. Kemp, Bell Telephone Laboratories, Incorporated, New York, N. Y.

Dealing entirely with soft rubber compounds, "this report shows the extreme effect of moisture distributed heterogeneously in rubber in association with conducting substances on the dielectric properties. The loss in the insulating value of crude rubber upon exposure to water is explained on the basis of its latex particle structure with the impurities and moisture located in the particle interface forming a continuous phase . . . milling and vulcanizing crude rubber results in stabilizing its dielectric properties when the rubber is exposed to water. Rubber and gutta percha are shown to be nonpolar substances which are not appreciably affected by large contents of moisture." The effect of fillers and pigments on dielectric properties of soft vulcanized rubber are described.

SURFACE CHARACTERISTICS OF FIBROUS INSULATION, K. S. Wyatt (A'32), The Detroit Edison Company, Detroit, Mich., and W. F. Davidson (A'14, F'26), Consolidated Edison Company of New York, Inc., New York, N. Y.

Outlining some of the problems concerning utility operating companies in determining the characteristics contributing to failure of fiber insulation, the methods of failure are described, and several practical tests for analyzing and predetermining such failures are indicated. Following the formal presentation of the paper by Mr. Davidson, co-author Wyatt spoke briefly about the correlation between the amount of gas involved and the life of paper impregnated with oil, describing some of the European studies of the subject. Quoting Van Dycke, a research engineer at The Hague, Netherlands, Mr. Wyatt pointed out that "there is a correlation between life and gas generation as determined by the method with hydrogen pressure; in proportion as the gas generation of the oil is greater, the life of the paper impregnated with it is shorter. This correlation does not exist with the methods at low pressure."

Allis-Chalmers Photo

**A demountable metal-tank mercury-arc rectifier embodying the characteristics of commercial-size equipment is used in the study of electronics in the laboratories of Massachusetts Institute of Technology, Cambridge; similar equipment is said to have been installed at Cornell, Harvard, Columbia, and other colleges**

THE EFFECT OF THE SURFACES OF THE ELECTRODES ON POWER FACTOR OF AN AIR CAPACITOR, A. V. Astin, National Bureau of Standards, Washington, D. C.

An extension of the National Bureau of Standards research work described at the 1936 meeting. Although no solid is included between the plates of an air capacitor, the capacitor has an appreciable power factor, because of surface characteristics of the plate. The 1936 report included investigations of only 4 materials for plates; the present paper, including a description of the effect of relative humidity on power factors, gives results for 10 materials. With aluminum plates a negative phase-defect angle at high humidity was observed, and was found to be more marked for large plate spacing than for smaller spacing.

THE POWER FACTOR OF AIR CAPACITORS, W. B. Kouwenhoven (A'06, F'34) and E. L. Lotz (Enrolled Student), The Johns Hopkins University, Baltimore, Md.

Although describing independent research work done at The Johns Hopkins University, scope is almost identical with preceding paper.

THERMAL BREAKDOWN OF PLASTIC INSULATING MATERIALS, R. M. Fuoss, General Electric Company, Schenectady, N. Y.

A continuation of investigations described at the recent Rochester meeting of the subcommittee on chemistry, this investigation embraced changes of resistance with changes in voltage caused by thermal variation. The thermal failures observed were caused by passage of current alone, not by puncture, and were found to be independent of thickness of the sample.

STUDIES OF BREAKDOWN IN COMPRESSED GASES, Alvin Howell (A'35) Massachusetts Institute of Technology, Cambridge.

Describing the breakdown of compressed air at voltages up to 500 kv and at high pressures, using direct current exclusively. The breakdown characteristics of gaps having various surface configurations have been studied, the characteristics of a gap consisting of a needle point opposite a plane being especially important, because such gaps are used in the Van de Graaf generators constructed at MIT. Present investigations indicate that such generators will not work well in compressed air at pressures above 200 pounds per square inch. In general, generators using compressed air may be made much smaller than the open-air type.

Third Technical Session—High-Voltage Insulation

MEASURING RATES OF OIL FLOW THROUGH PAPER, H. H. Race (A'24, M'31), General Electric Company, Schenectady, N. Y.

A description of the methods of measuring the rate of oil flow through flat sheets of paper in vacuum, to avoid inclusion of gas flow in the measurements. The method was extended to predict oil-flow characteristics by means of air-flow data.

PAPER-TO-OIL RATIO IN CABLES, E. W. Greenfield (A'34) Anaconda Wire and Cable Company, Hastings-on-Hudson, N. Y.

Because the ionization of power cables takes place in the voids in the insulation, the accurate determination of the most effective ratio of paper to voids is very important. Approaching these problems from a fundamental point of view, mathematical and experimental methods of determining the most effective arrangements of oil and paper layers are described.

STABILITY OF CABLE OILS EXPOSED TO ELECTRICAL DISCHARGE IN VACUUM, W. A. Del Mar (A'06, F'20), John H. Palmer (A'29), and E. J. Merrill, Habirshaw Cable and Wire Corporation, Yonkers, N. Y.

A description of oil-stability characteristics during accelerated life tests as used on power cables. Oils having stable gassing characteristics usually have somewhat unstable power-factor characteristics under electrical discharge in vacuum.

OIL OXIDATION IN IMPREGNATED PAPER, J. B. Whitehead, The Johns Hopkins University, Baltimore, Md., and T. B. Jones, Bell Telephone Laboratories, Incorporated, New York, N. Y.

A report of a series of studies of the oxidation process in cable paper impregnated with oil containing different amounts of oxygen, as indicated by changes in well-known electrical quantities. Separate studies of the effect of equal amounts of air and of nitrogen, of the behavior of the oil alone, and as affected by paper and metal, show something about the nature of the progressive changes found in the electrical characteristics. [*See pages 1492–1502, this issue.*]

STABILITY OF OIL-TREATED INSULATION, H. W. Bousman (A'25, M'36), General Electric Company, Schenectady, N. Y.

A long life test may not be the most important factor in judging an oil for use in a cable, for the

"specific optical dispersion of oil is known to be related to the life of oil-impregnated paper."

ELECTRICAL CHARACTERISTICS OF IONIZED GAS FILMS, C. L. Dawes (A'12, F'35), Harvard University, Cambridge, Mass.

Describes methods of measuring characteristics of ionized gas films. A capacitance method was used instead of a mechanical method for determining thickness of the gas films.

MECHANICAL UNIFORMITY OF CABLE INSULATION AND METHODS FOR ITS MEASUREMENT, K. S. Wyatt, The Detroit Edison Company, Detroit, Mich.

Ionization at the low stresses used in cables must take place between the layers. This report describes a method of examining these interstices without mechanical deformation of the layers. The specimen is "embalmed" in styrene, and wafer-like samples sawed from the specimen are translucent, being easily examined without complex equipment. "The uniformity of most electrical characteristics is dependent upon mechanical uniformity of the cable."

# The Institute Budget for the Year 1937-38

ALTHOUGH the members are familiar with the financial condition of the Institute, having seen the annual directors' report in the July issue of ELECTRICAL ENGINEERING, it is felt that many would appreciate a more detailed accounting of the $299,500 budget for the year ending September 30, 1938.

Accordingly, the following tabulation of estimated income and disbursements, adopted by the board of directors on October 28, 1937, is presented with comments which it is hoped will adequately explain the scope and purpose of those appropriations in which the membership is most vitally interested.

## PUBLICATIONS

*Electrical Engineering — Transactions.* The budget provides for the publication of an increased number of technical-program papers and general-interest articles. During the last appropriation year, 1,594 pages were used and 1,785 pages are planned for the current year—an increase of about 12 per cent. The appropriation for this purpose is approximately $83,300 as compared with an expense of approximately $77,800 for the preceding year—an increase of about 7 per cent. Roughly two-thirds of the increased cost results from the increased number of pages, the remaining third resulting from increased circulation and higher material costs.

The study of publication policy undertaken by the publication committee about a year ago, has been completed, with the co-operation of the technical program committee, and the recommendations were acted upon at the October meeting of the board of directors. The budget as adopted is based on the recommended revisions in publication policy and includes an appropriation of $7,900 to provide preprints of the accepted manuscripts of all papers for national meetings and papers approved by the technical program committee for District meeting programs. A limited number of these preprints will be provided without charge for the use of authors and the technical committees. Others may purchase them for five cents each at headquarters and at the registration desk at meetings, or for ten cents each by mail. There will be published regularly in ELECTRICAL ENGINEERING a list of preprints available.

Other provisions of the revised publication policy and the budget call for the publication in full in ELECTRICAL ENGINEERING of two-thirds of all technical-program papers and for the publication in ELECTRICAL ENGINEERING of the other third in "rewrite" or "abstract" form. TRANSACTIONS will include all formal technical-program papers in full and correlated with the approved discussions. Notwithstanding the increased number of pages and the increased material costs, the subscription price of TRANSACTIONS will be $4.00 as it has been in the recent past.

Additional information concerning the revised publication policy will be found in the November 1937 issue of ELECTRICAL ENGINEERING, page 1409.

*Yearbook.* An up-to-date revision of the YEARBOOK will be issued again this year and the budget includes approximately $6,800 for this purpose. Copies of the YEARBOOK are available without charge to members on request. An announcement will appear in the news columns of ELECTRICAL ENGINEERING when the book is ready for distribution.

## INSTITUTE MEETINGS

In conjunction with the publication of technical papers and discussions, the national and District meetings of the Institute, as well as the meetings of Sections, provide the greatest opportunity for the realization of Institute objectives. In organization work—whether it be social, political, trade, or the work of a professional group similar to the Institute—effectiveness of operation is measured to a great extent by the membership contact provided.

The appropriation for meetings' activities for the coming year is intended to cover particularly the routine printing and supplies expenses of the Middle Eastern District meeting, which was held in Akron, Ohio, October 13–15, 1937, the winter convention in New York City, January 24–28, 1938, the North Eastern District meeting to be held in Pittsfield, Mass., in May, the summer convention in Washington, D. C., June 20–24, 1938, and the Pacific Coast convention which will be held in Portland, Oregon, August 9–12, 1938. In addition, the appropriation takes care of those expenses of the 1937 Pacific Coast convention which were not reimbursed until after accounts were closed for the 1936–37 year, as well as routine expenses incurred at Institute headquarters and chargeable directly to meetings' activities.

In considering the amount appropriated for Institute meetings, attention must also be given to the provision for traveling expenses of Section and Branch delegates (see paragraph dealing with traveling expenses) who, together with the officers and members in attendance at the summer convention, hold an annual conference for the interchange of ideas and experiences. Of late years the scope of these conferences has broadened so that a considerable part of the discussion deals with topics of interest not only to members residing within Section territory but to the entire membership—in many cases the recommendations of the conference leading to the adoption of policies which are expected to enhance the benefits of membership and the usefulness of the organization.

## INSTITUTE SECTIONS

The major portion of the appropriation for Institute Sections is intended to cover the expenses of meetings as held during the year by 64 Section organizations. The By-Laws provide for a flat appropriation of $175 for each Section, plus an allowance of $1 for each active member residing within the territory of the Section on August 1.

As shown in the tabulation, other expenditures, charged directly to Institute Sections, comprise the cost of printing and supplies furnished by headquarters throughout the year, and that proportion of the headquarters' staff payroll which is allocated to Section activities.

## INSTITUTE BRANCHES

One hundred twenty Branches of the Institute are now established in schools of recognized standing throughout the country, where students hold regular meetings, as do the members in Institute Sections. The budget provides for the reimbursement of purely meeting expenses, the cost of necessary supplies for carrying on routine Branch work, and that portion of salary expense at headquarters which represents the time entirely devoted to Branch activities.

The appropriation for Institute Branches also provides for the reimbursemnt of miscellaneous expenses which develop incidental to Student conferences and conventions. Payments are not made to the individual Branches but to the committee in charge of a conference and cover the actual expenditures within a limitation of an appropriation of $5 for each Branch participating in the meeting.

## COMMITTEES

In view of the official record of Institute activities, as contained in the monthly journal, ELECTRICAL ENGINEERING, it is probably unnecessary to dwell upon the scope of the appropriations for the different committees of the organization. Nevertheless, a few comments regarding the larger appropriations may be of interest, as follows:

*Finance Committee.* For the third consecutive year the budget provides for the

engagement of investment counsel services, in an effort to insure the stability and security of Institute investments for the reserve capital fund, as well as for the special funds for which the Institute has accepted the responsibility of trusteeship. In addition, the appropriation takes care of the expense of the annual audit of Institute accounts for the fiscal year ending April 30, a report of which appears in ELECTRICAL ENGINEERING for July 1937.

*Membership Committee.* The work of this committee in bringing the advantages of membership to the attention of desirable candidates continues along much the same lines each year; therefore, a considerable portion of the committee's appropriation is devoted to the printing of necessary application forms and other membership literature describing the aims of the Institute. The distribution of this literature is handled almost entirely by the 64 local Section membership committees under the general direction of the national committee.

As shown in the annual report of the board of directors, 1,756 new applications were received during the last fiscal year, many from persons whose names were proposed for membership as a result of the communications addressed by the national committee to the general membership. The expense of the clerical work at headquarters in handling these applications, as well as the routine correspondence with Section membership committees, with members concerning the status of their affiliations, with Enrolled Students eligible for advancement to the Associate grade, etc., constitutes a charge to the appropriation. One other item is worthy of mention, i.e., the special payment of a portion of the entrance fee to the Section in which a new member is located, estimated to require this year at least $1,400 of the committee's appropriation.

*Standards Committee.* The activities of the standards committee for the past year have been so fully related in the annual report of the board of directors published in the July issue of ELECTRICAL ENGINEERING that further comment should perhaps be confined to the plans of the committee for the revision and printing of new editions of 11 standards, as mentioned below:

Measurement of Test Voltages in Dielectric Tests
Industrial Control Apparatus
Graphical Symbols
Automatic Stations
Electrical Measuring Instruments
Insulators
Indicating Instruments
Electrical Recording Instruments
Electrical Installations on Shipboard
Test Code for D-C Machines
Test Code for Apparatus Noise Measurement

The preliminary expense for composition and other printing expenses on account of the above-mentioned revisions will be charged to the appropriation of the standards committee, in addition to any miscellaneous charges and that portion of the headquarters' payroll which reflects the time devoted to the work of the committee.

*Technical Committees.* It has not been necessary to make separate appropriations for the technical committees inasmuch as all of the expenses of printing technical papers, under existing publication policies, has been chargeable to the publication committee. A nominal appropriation of $250, therefore, covers principally the expense of providing committee stationery and also minor expenses which will arise during the year. However, with the inauguration of the plan to reproduce authors' manuscripts, already mentioned, it is probable that $1,000 of the appropriation of $7,900 for such preprints will be transferred to the appropriation for technical committees, for use in reproducing those papers which are not intended for publication in the annual TRANSACTIONS.

### TRAVELING EXPENSES

The budget again provides for reimbursement of substantially all the expense incurred for railroad fare, Pullman accommodations and meals en route, in the traveling allowance to District, Section, and Branch representatives, to members of the board of directors, and to members of the national nominating committee. The traveling allowances are reimbursed on a uniform rate of 7 1/2 cents per mile, one way, mileage being obtained from the Official Table of Distances compiled by the United States War Department. The authorized traveling expense appropriations are as follows:

1. For each vice-president of the Institute to one meeting each year of each Section and each Student Branch within his geographical District, it being understood that joint meetings of Sections and Branches will be arranged as far as may be expedient.

2. For the vice-president, the District secretary, the vice-chairman of the national membership committee located in the District, the chairman of the District committee on Student activities, and the chairman and secretary of each Section within a District (or, if neither can attend, an alternate chosen by the executive committee of the Section) to one meeting each year of the District executive committee held within the District.

3. For the vice-president and secretary of each District, the counselor and the incoming Student chairman of each Branch within the District, and the appointed member of the committee on Student Branches located in the District to one conference on Student activities within the District each year under the auspices of the committee on Student activities of the District. Alternates for counselors not authorized. The allowance is available to alternates for Branch chairmen only upon advance approval by the vice-president of the District in each case.

4. For one delegate from each Section to the annual summer convention.

5. For all District secretaries to the annual summer convention.

6. For one Student Branch counselor from each District, to represent the committee on Student activities of the District, to the annual summer convention.

7. For all members of the national nominating committee to the annual meeting of the committee, held during the winter convention.

**Table I. Institute Income and Expenses for Year Ending September 30, 1937, and Budget for Year Ending September 30, 1938**

| | Actual Income and Expenses, Year Ending 9-30-37 | Budget for Year Ending 9-30-38 |
|---|---|---|
| **Income** | | |
| Dues | $195,963.61 | $207,300.00 |
| Students' fees | 11,028.00 | 11,000.00 |
| Entrance fees | 7,468.15 | 7,000.00 |
| Transfer fees | 855.25 | 1,000.00 |

| Retirement salary | 2,700.00 | 2,700.00 |
| Miscellaneous | 416.18 | 310.00 |
| Total | $268,730.50 | $298,959.00 |

8. For members of the board of directors and the executive committee to meetings of the respective bodies.

It will be noted that the traveling expense allowance has been restored for both the chairman and secretary of each Section within a District in attendance at the annual meeting of the District executive committee, whereas the budget allowance during recent years provided for the attendance of but one representative from each Section. In addition, an allowance for traveling expense has been provided to the vice-chairman of the national membership committee, who is now a member of the executive committee in his respective geographical District.

### Administration

The duties of the headquarters staff being closely interwoven with the activities of the 24 standing administrative committees and 18 technical committees, it is easy to understand the allocation to this appropriation of approximately 41 per cent of the total of salaries paid to those members of the staff whose compensation is not chargeable elsewhere in the budget. This item also absorbs the full salaries of the national secretary and office manager, and temporarily includes an appropriation of $2,500 for authorized additions to the staff required by extra duties to be performed for Institute committees and to relieve a congestion of work which develops in some departments at certain seasons of the year; as this expense is incurred later it will be reallocated to the committee or other activity involved. The Institute still maintains the smallest staff per 1,000 members of any of the Founder Societies.

The work of general administration, joint activities, secretarial, and other duties for committees is so broad as to make it difficult to describe the specific services required of the staff within the limitations of space for this article.

### Prizes for Papers

On account of the severe effects of the depression upon Institute finances, the board of directors discontinued in the fall of 1932 all cash payments in connection with prizes for papers except those accompanying District Branch paper prizes. Upon the recommendation of the committee on Institute prizes, the board has restored in this year's budget the cash awards of $100 each for the national prize for initial paper and the national prize for Branch paper, as well as the award of $25 for the District prize for initial paper in each district. The budget again provides for the cash award of $25 for the District prize for Branch paper in each District, and for the issuance of certificates of award to the recipients of all other prizes.

### Joint Activities

The activities in which the Institute is engaged jointly with other engineering organizations are many and varied and have been so frequently brought to the attention of the membership through the news columns of the monthly journal that it is probably unnecessary to comment on the provisions of the budget for such activities beyond a statement of the amount expended last year and the anticipated expense for the present year. It will be noted that the Institute will contribute toward the support of American Engineering Council the same sum as during the preceding year. With respect to the joint activities which are internal in nature, it will be observed that the appropriation for the support of the Engineering Societies Library has increased in proportion to the higher membership figures as of the present year, and also that the assessment paid to United Engineering Trustees is calculated upon a basis which permits of the desired annual reserve for the depreciation and renewal fund.

### Other Appropriations

The remaining items in the budget are self-explanatory in nature, and for the present appropriation year beginning October 1, 1937, involve but a small percentage of the estimated total disbursements.

In closing these comments regarding the proposed expenditure of Institute income, mention should be made that during the year ending September 30, 1937, the board of directors authorized the transfer of $7,500 from general funds to the reserve capital fund, for investment purposes; a similar transfer was authorized at the meeting of the board held on October 28, 1937.

As stated in the budget message of President Harrison, printed elsewhere in this issue, the board of directors has adopted a budget of expenditures for the coming year which appropriates practically all of the estimated income for the corresponding period, and which is substantially in excess of the amount expended last year. It is the expectation of the board, however, that the resultant benefits to the entire membership will fully justify the increased expenditures. Each year the board of directors and finance committee endeavor to adopt a budget that places the proper emphasis on the different phases of Institute activities and which limits the annual expenditures to the total of anticipated yearly income. Membership dues, of course, comprise the principal source of Institute revenue, so that the success of all work planned for in the budget virtually depends upon the prompt collection of dues. It is gratifying to know that this situation is realized by the membership, as evidenced by the fact that the number who are in arrears for dues as of this date is at the lowest figure for several years.

**Civil Engineer Honored.** Arthur S. Tuttle, former head of the engineering force of the city of New York, N. Y., recently was awarded a certificate of distinguished service. The award was made by Mayor F. H. Laguardia before a large group of engineers and city officials assembled in the chambers of the Board of Estimate and Apportionment, the body that Mr. Tuttle had served as principal assistant engineer, deputy chief engineer, chief engineer, and consulting engineer for over 30 years. In presenting the certificate, the mayor stated that this is an age in which special training is an essential qualification for public office and that Mr. Tuttle's distinguished service to the city stands out as an example of what can be accomplished by obtaining the right men for such service. Mr. Tuttle is a life member of the American Society of Civil Engineers, and has served that society as treasurer, 1919–1920, vice-president, 1932–33: and president, 1935.

## More Hydro Power Scheduled for Texas

Preliminary plans incident to the proposed rehabilitation of the Austin Dam located on the Colorado River (of Texas) at Austin contemplate reconstruction of the dam to a height of 63 feet and the construction of a new power house on the west side of the river with an initial hydroelectric generating capacity of some 6,250 kw. Another 6,250 kw installation is planned for the Marshall Ford Dam, some 12 miles upstream from Austin, when that dam shall have been completed and adequate water becomes available.

Under the terms of a proposed agreement between the City of Austin and the Colorado River authority, the Austin Dam rehabilitation will be undertaken by the authority at a cost of about $1,800,000 financed by a PWA loan and grant. The authority is to lease the dam from the city for a 30 year period, furnishing $20,000 worth of free power to the city as rental. The original Austin Dam was finished in 1893, and destroyed by flood in 1900; it was reconstructed in 1911 but never accepted by the city. Through a court decree the city obtained the title in 1934.

**Annual Science Exhibition.** In concurrence with the annual meetings of several scientific organizations, the annual science exhibit of the American Association for the Advancement of Science is to be held at the Murat Theater, Indianapolis, Ind., December 27–30, 1937. Besides the product displays of various companies the exhibition will feature the recent scientific discoveries of individual investigators and noncommercial research organizations. Among these exhibits will be specimens of equipment used for the measurement of cosmic rays, samples of "heavy" water, and a series of photographs of a recent solar eclipse made by means of new and improved cameras built especially for the purpose.

**Poems by Prominent Member.** A collection of poems written during the past 25 years by Vladimir Karapetoff (A'03, F'12, Life Member) professor of electrical engineering at Cornell University, has been published under the title of "Rhythmical Tales of Stormy Years." The poems are classified under Lyrical, The Immigrant's Fun, A Crazy Quilt, Religious, Philosophy of Life, and Translations from the Russian. Some of the poems have appeared in various periodicals or been recited at conventions. Copies may be obtained from the Cornell Co-operative Society, Ithaca, N. Y.

# Effective Joint Action Among Technical Groups in Cincinnati

By dealing only with the broadest interests of its participating societies, the Technical Scientific Societies Council of Cincinnati, Ohio, has achieved notable success in the promotion of joint activities among technical and scientific groups in that city. The effectiveness of the carefully mapped plan of organization, which brings together in this co-operative effort ten organizations comprising a total of some 1,500 members, is evidenced by the fact that in the two years since the council was organized no serious difficulties have developed, growth and progress alone being noted. With the thought that the experience of the Cincinnati Council might be of assistance elsewhere, L. R. Culver, chairman of the AIEE Cincinnati Section (one of the participating bodies) has prepared the accompanying article which describes not only the final arrangements and results, but also the more difficult preliminary steps that were necessary to assure smooth sailing during the organization period.

The idea of closer contact and mutual support among groups of the Institute type was not new, even locally. There were or had been, in Cincinnati as well as in other large centers, more or less satisfactory local affiliations; it was considered desirable to analyze their difficulties and accomplishments as the preliminary step, before approaching all the groups whose co-operation was desired. Particular attention was given to the reasons for the collapse of previous aggregations of societies. Two elements appeared to be responsible for most of the bickering on the one hand, and lack of interest on the other, with eventual disbandment in either event: (1) too much centralization of authority in one of the participating societies, especially in financial matters; and (2) too few points of contact through which to maintain mutual interest. To forestall these troubles, the organizers in Cincinnati set as their guiding principles that no participating society would suffer any loss of autonomy, that the idea of joint progress and support would be kept actively alive by having several operating committees with definite duties and full representation, and finally that the whole structure would be explicitly subservient to its component parts.

By adhering strictly to the principles laid down, the organizers encountered little or no difficulty in convincing the principal members of the technical community that everything was to be gained by the formation of a technical council among them to promote their joint interests. Included in the program were publishing of notices, sponsoring of joint meetings, reducing of duplication of services, stressing of mutual aims, exchanging of information in overlapping fields of interest and, in general, eliminating sources of conflict while promoting friendly intercourse.

Changing conditions bring changing need no less in the scientific world than elsewhere. With this premise, the organizing committee conducted its work throughout the summer of 1935, laying down a code in which the societies defined their mutual relationships and established their council, restricting their pronouncements to stating their aims and the duties of the several operating committees. By-laws were not framed; in their place the salient actions of the governing committees are preserved for ready reference, as guides but not as mandates for the future. That the organization was carefully mapped out may be realized from the fact that two whole years of operation have disclosed no "sore spots," growth and progress alone being noted. In fact, the code has been revised only once and then only in very minor respects, principally in clarifying the wording.

It may be debatable that the experience of some 1,500 members of ten co-operating societies in Cincinnati may be used elsewhere, perhaps nationally, as a guide to effective group effort. The societies, however, feel that they have dealt only with the broadest interests in establishing their council. They offer the following code for study and, if found suitable, adoption by other technical and scientific groups. No attempt is made to analyze its parts, to point out its restricting clauses or to show how the committees are interrelated; if it requires such interpretation, it fails in its purpose.

### Section I—Name

1.01 The co-operative body of the technical societies of Cincinnati shall be known as the Technical and Scientific Societies Council of Cincinnati, hereinafter designated the Council.

### Section II—Purpose

2.01 The purpose of the Council shall be to bring together for co-operative effort in rendering more and better service and in furthering scientific and technical activities, the technical societies of the Cincinnati district, which have as their purpose the maintenance of a high professional standing.

2.02 The Council shall have no jurisdiction over the meetings or actions of the constituent societies individually or jointly, its purpose being limited to the co-ordination of the societies' activities.

### Section III—Participating Societies

3.01 The following societies are member organizations of the Council:

| | |
|---|---|
| ACS | American Chemical Society |
| AIEE | American Institute of Electrical Engineers |
| ASCE | American Society of Civil Engineers |
| ASHVE | American Society of Heating and Ventilating Engineers |
| ASM | American Society for Metals |
| ASME | American Society of Mechanical Engineers |
| ECC | Engineers' Club of Cincinnati |
| IES | Illuminating Engineering Society |
| IRE | Institute of Radio Engineers |
| SAME | Society of American Military Engineers |

3.02 The governing committee of the Council shall be empowered to approve requests of other qualified societies for participation in the Council. This committee shall also be empowered to accept the withdrawal of any society or for just cause to request the withdrawal of any society.

### Section IV—Administration

4.01 The administrative affairs of the Council shall be executed by the following committees:

A. Policy committee
B. Program co-ordination committee
C. Publication committee
D. Executive committee

4.02 The policy committee shall be the governing committee of the Council and shall consist of the presiding officers of the participating societies, the chairman of the Council's program co-ordination committee, the chairman of the Council's publication committee, secretary-treasurer of the Council, and two members-at-large.

4.03 The program co-ordination committee shall consist of representatives—one from each society—qualified to act upon their respective program and meeting-arrangement matters. It shall be the duty of this committee so to arrange the programs of the several societies as to reduce conflicts in dates, to encourage joint meetings of two or more societies and generally to promote effective co-ordination of their activities.

4.04 The publication committee shall consist of representatives—one from each society—qualified to act upon publication matters, and the editor of the Council's publication whenever such officer is appointed by the policy committee. It shall be the duty of this committee to prepare and distribute suitable publication material, including the announcements of the meetings of the constituent societies and such other items as the Council may devise.

4.05 The executive committee shall consist of the president of the Council who shall act as chairman, chairman of the program co-ordination committee who shall act as vice-chairman, chairman of the publication committee, secretary-treasurer of the Council, two members of the policy committee selected by that committee, and the junior past-president of the Council. It shall be the duty of this committee to supervise, initiate, and direct in detail the affairs of the Council on behalf, and subject to the approval, of the policy committee. In the event that a member of the executive committee is unable to perform his duties, the policy committee shall appoint a substitute to serve out his term, at the request of the president.

4.06 The chairmen of the several committees and the secretary-treasurer shall serve for a period of one year without re-election. However, each shall serve until his successor has taken office. All positions shall be honorary excepting that of editor.

4.07 Each society shall name, and report to the secretary of the Council, its representatives on the committees before September 1 of each year. Then an organization meeting shall be held by each committee not later than the 20th of September. Each committee meeting shall be called to order by its retiring chairman who first shall present a report of his committee work and make such recommendations as he desires. The retiring chairmen of the program co-ordination and publication committees then shall conduct secret ballot elections of their successors. The new chairmen of these two committees then shall take charge of their meetings and conduct their business, including elections of secretaries if the committees so desire.

4.08 At the organization meeting of the policy committee, after making his report and recommendations, the retiring chairmen shall conduct secret ballot elections of the following officers in the order given:

A. Two members-at-large of the policy committee, to be chosen from the membership in good standing in the constituent societies.

B. President of the Council (who serves as chairman of the policy and executive committees).

C. Secretary-treasurer of the Council (who serves as secretary of the policy and executive committees) to be chosen from the membership in good standing in the constituent societies and not necessarily otherwise a member of the policy committee.

D. One member of the policy committee to serve as member-at-large on the executive committee for a term of two years.

4.09 Each committee shall hold throughout the year such further meetings as may be required, or called by its chairman, but meetings in January and May at least are mandatory.

4.10 The secretary-treasurer of the Council shall perform the customary duties pertaining to his office, but shall be required to submit a financial report at the May meeting of the policy committee. Also, he shall be required to maintain an up-to-date digest of the important actions of the policy and executive committees, including those of earlier years, and to convey this digest to his successor at the organization meeting of the policy committee.

### Section V—Finances

5.01 The stated expenses of the Council shall be limited to expense in connection with the publication. They shall be apportioned equitably on

the basis of the services rendered. Each organization's proportionate share of the publication expenses shall be determined on an annual basis.

5.02 Any other expenditure must be approved by the policy committee.

SECTION VI—CODE REVISION

6.01 Code revisions involving financial considerations may be enacted or adopted by a three-fourths vote of the policy committee.

6.02 Such other regulations as may be necessary for the conduct of the business of the Council may be enacted or approved by majority vote of those present at any policy committee meeting.

In conclusion, it should be pointed out that the council started with a four-page monthly publication; this is now expanded to 24 pages and it reaches the membership at less cost than the four-page original. This publication, *The Cincinnati Engineer and Scientist*, supports a part-time editor and prints items of common interest in addition to the notices concerning the societies individually. For the present the publication schedule includes ten monthly issues from September through June, and a directory issue released during the summer interval. The 1937 directory includes a dual, alphabetical listing of the entire membership which required a 72-page issue. An innovation recently introduced consists of a gummed strip bound into the center of the publication and divided into sections by perforations; in these sections are printed the emblems of the various societies with associated current meeting dates and places, so that those who wish may detach the sections containing notices of meetings they plan to attend and stick them, in stamp fashion, to their appointment calendars as final reminders.

In addition to publication and other routine duties, the Council has arranged annual joint meetings of all societies at which the average attendance has been over 2,500. These concrete examples of the growth of the movement in Cincinnati are offered as an indication of its merits. It is believed that the general plan can be employed usefully elsewhere.

**ASHVE to Hold Meeting.** The 44th annual meeting of the American Society of Heating and Ventilating Engineers will be held at New York, N. Y., during the week of January 24, 1938. Joint sessions are planned with the American Society of Refrigerating Engineers and the National Warm Air Heating and Air Conditioning Association. The fifth International Heating and Ventilating Exposition also will be held concurrently at Grand Central Palace.

# Current Items From American Engineering Council

## A Public Works Department

Definite recommendations for a public works department to be created in the process of government reorganization which is still before Congress are to have consideration during the eighteenth annual meeting of the American Engineering Council's assembly in Washington, D. C., January 13–15, 1938. Special studies by the staff and a comprehensive report of the AEC public works committee regarding the structure of a public works department are to be ready for discussion at that time.

Engineers have advocated a public works department for many years and now that the President's committee on administrative management has also recommended the creation of a public works department, engineers are encouraged to believe that the proposal may be due for serious consideration by this next session of Congress. It is not likely to be without opposition, however, because even the Brookings Institution which made a study for Senator Byrd's committee, failed to support the idea although they did recommend many changes in public works and engineering functions.

One of the major problems is to determine what is public works and to name those bureaus or activities among federal government agencies which should be included in the initial structure of a public works department. The President's committee came to the conclusion that such a department should "advise the President with regard to public works" and that it should be prepared to serve other government agencies as indicated in the following quotation:

"To design, construct and maintain large-scale public works, which are not incidental to the normal work of other departments, except as their agent on request; to administer federal grants, if any, to state and local governments or other agencies for construction purposes, and to gather information with regard to public works standard throughout the nation."

The complexity of the problem is indicated by the fact that neither one of the more recent studies undertook to name those engineering or public works agencies or functions which should be drawn together into a public works department. The President's committee concluded its suggestion, as follows: "The committee does not assign to the new department particular agencies and bureaus, but leaves this assignment to the Executive when, and if, the Congress enacts a law setting up the general departmental structure."

Conditions with reference to "public works" have changed materially in recent years, and engineers in both public and private life have made many observations and acquired a vast amount of actual experience with public works programs. Recognizing that fact, American Engineering Council is anxious to help to unite engineers in their public responsibility with reference to public works activities undertaken by the federal government, the several states, and local committees. To that end, engineers and engineering organizations are invited to express themselves to the AEC public works committee.

## Scientific Research Legislation

The American Engineering Council has appointed a special committee to consider the ramifications of Congressman Randolph's H.R. 7939 for the promotion and coordination of scientific research activities as a means for the prevention of unemployment in the future. Congressman Randolph seems to be leading a school of thought which publicly subscribes to the philosophy that an even greater application of technology to industry and business is necessary to insure that expansion of capital outlets which guarantees an increasing volume of employment.

Although the Randolph bill has not come up for action in Congress and is still subject to change, it has aroused much interest among members of the engineering profession. A number of engineers have already filed criticisms and suggestions, and Randolph informs us that he is anxious to have reactions representing all fields of technology. Council has not formulated an official policy with reference to this legislation but the following observations are made available for the convenience of those engineers and engineering organizations who may be concerned about either federal government support or control of research in both pure and applied science.

In essence, Congressman Randolph proposes that instead of having a variety of research projects carried on by government bureaus and special research agencies seeking government funds in an unplanned way for their particular projects, these various efforts be co-ordinated through the establishment of an advisory board made up of representatives of the government, of scientists, and of industry. That approach to the problem has appealed to this organization.

Last year the land-grant colleges introduced a bill proposing the establishment of engineering experiment stations in each state paralleling in general the agricultural experiment station idea. Since the land-grant act is administered through the Agricultural Department, the land-grant colleges believe that any development of such experiment stations should be so administered. Meanwhile the state colleges in 19 states—in some of which there are also land-grant colleges—sought to have this bill modified so that money could be spent at state colleges as well as at land-grant colleges in particular states. In this proposal, the administrative machinery would be located in the Bureau of Standards of the United States Department of Commerce.

A third bill confused the issue further by proposing a plan for government expenditures in the field of business research, this one to be headed in the Department of Commerce. Each of these bills has had the active support in Congress of the particular group of representatives of educational associations, the land-grant colleges having a committee and the state colleges another, the business schools having a third. Mean-

while, of course, certain government bureaus, like the Bureau of Standards and the Bureau of Mines, seek money for fundamental research, and sometimes the regular functions of the government in their research efforts are confused with the proposals outlined above. So far, it has been impossible to secure a meeting of minds between the college groups. Within certain states, there is a feeling of sharp competition, and as a result in earlier years none of the bills have succeeded in passing largely because there has been no meeting of minds in the state by which the Congressman in that state could be induced to take action.

It seems that Congressman Randolph is approaching this matter in a way in which some order might be brought out of this chaos. While the American Engineering council has not committed itself to any detail of the bills, we have been assisting Mr. Randolph in securing all the information he can from all the sources, so he will have before him as complete a picture of the problem as possible before he revises his bill. Our understanding is that Congressman Randolph has the friendly support of the President in his efforts, and this seemed to be an added reason, if anything was to be done in this matter, for working with Mr. Randolph in perfecting his legislation.

## Accurate Maps and Public Works

In response to an invitation from the Federal Board of Surveys and Maps, the American Engineering Council, through its committee on surveys and maps, has prepared the following statement to be used by a special committee in an effort to have the "mapping agencies" seek additional appropriations from Congress for the acceleration of "basic mapping" under the Temple Act during the fiscal year ending June 30, 1939.

"American Engineering Council has for many years vigorously supported, in the public interest, the requests of our member engineering organizations that the basic map of the United States be completed at the earliest possible date. As a move in the right direction, American Engineering Council has accepted, in principle, the recommendations made by Secretary Ickes in response to Senate Resolution 281 which requested a program for expediting the topographic mapping of the United States. The recommendations involve a 20-year program and the expenditure of $100,000,000. They would give the Geological Survey $4,000,000 for topographic surveys and maps, and the Coast and Geodetic Survey $1,000,000 for first and second order control surveys in 1938 under such items as the directors of the surveys may designate.

"The committee on surveys and maps of American Engineering Council earnestly hopes that steps will be taken by the Bureau of the Budget and the Congress to appropriate the minimum of $5,000,000 that is called for in this program. They believe that in the interest of public economy, of present immediate need, and of the future conservation of our national resources, this step should be taken.

"Earlier communications from American Engineering Council to the President, to the committees of the House and Senate, and to the various federal and state agencies involved, have pointed out that the fulfilment of original Temple Act passed in February 1925 and supported uuanimously by map makers and map users alike, is long overdue. We can think of no more practical contribution to both national economy in a broad sense of planning and national economy in a strict budgetary sense than can be made by the administration and by the Congress at this time. . . .

"The committee, in supporting this first step toward an adequate mapping program, perceives it as only the beginning of a long desired objective and earnestly hopes that every effort be made to carry out the complete plan with additional appropriations annually of such size as will complete a basic map for the United States at the earliest possible date. The committee on surveys and maps of American Engineering Council wishes to record itself as willing to help forward this program in every proper way consistent with the great public desirability for fulfilment of a very real social and economic need for accurate knowledge of both horizontal locations and topography in all sections of this country."

# United Engineering Trustees, Inc.

## The Joint Engineering Organizations

United Engineering Trustees, Inc., was organized in 1904 as an instrumentality of the Founder Societies, the 4 national societies of civil, mining and metallurgical, mechanical, and electrical engineers. Its purpose is the managing of property and funds in which these societies have joint interests, and it is governed by trustees duly appointed by the societies as their representatives. It maintains 2 departments: (1) the Engineering Societies Library, and (2) The Engineering Foundation.

The corporation (UET, Inc.) manages the Engineering Societies Building and all trust funds placed in the hands of the United Engineering Trustees, Inc.

The Engineering Foundation, founded by the late Ambrose Swasey (HM'28) in 1914, is entrusted with the expenditure of income from endowment and other funds. The ultimate objective of Foundation is stated to be: "for the furtherance of research in science and engineering, or for the advancement in any other manner of the profession of engineering and the good of mankind."

The Engineering Societies Library is a free public engineering library, which, is operated for users at a distance, as well as for those who visit its rooms in the Engineering Societies Building.

In the accompanying articles may be found announcements of the elections recently held by UET and The Engineering Foundation, and abstracts of the annual reports of these organizations and of the Engineering Societies Library.

## Election of Officers of United Engineering Trustees, Inc.

Officers to serve the United Engineering Trustees, Inc., for the year 1937–38, were elected at the annual meeting of UET held in the Engineering Societies Building, New York, N. Y., October 28, 1937. D. Robert Yarnall, chief engineer of the Yarnall-Waring Company, manufacturers of power-plant specialties, Philadelphia, Pa., was elected president, and Albert Roberts and H. A. Lardner (A'94, F'13) were chosen vice-presidents. H. R. Woodrow (A'12, F'23) becomes treasurer, and J. P. H. Perry, assistant treasurer. John H. R. Arms, general manager, was re-elected secretary.

The names of all members of the board of trustees of UET for the year 1937–38, including both new and hold-over members, are as follows:

*Terms expiring October 1938*

| | |
|---|---|
| J. P. H. Perry | ASCE representative |
| H. A. Lardner | ASME representative |

*Terms expiring October 1939*

| | |
|---|---|
| J. P. Hogan | ASCE representative |
| Albert Roberts | AIME representative |
| D. Robert Yarnall | ASME representative |
| H. P. Charlesworth (M'22, F'28, past-president) | AIEE representative |

*Terms expiring October 1940*

| | |
|---|---|
| O. E. Hovey | ASCE representative |
| W. D. B. Motter, Jr. | AIME representative |
| K. H. Condit | ASME representative |
| H. R. Woodrow (A'12, F'23) | AIEE representative |

*Terms expiring October 1941*

| | |
|---|---|
| A. L. J. Queneau | AIME representative |
| F. M. Farmer (A'02, F'13, director) | AIEE representative |

Of these, O. E. Hovey, A. L. J. Queneau, and K. H. Condit became reappointed members at the annual meeting, upon presentation of credentials from the Founder Societies. W. D. B. Motter, Jr., fills the unexpired term of H. G. Moulton and H. A. Lardner fills the unexpired term of H. V. Coes. The following committees were appointed:

**Finance:** Albert Roberts, *chairman;* J. P. Hogan, H. A. Lardner, H. R. Woodrow, D. Robert Yarnall, *ex-officio.*

**Real Estate:** J. P. H. Perry, *chairman;* A. L. J. Queneau, K. H. Condit, H. P. Charlesworth, D. Robert Yarnall, *ex-officio.*

## Engineering Foundation Elects Officers

The annual meeting of The Engineering Foundation was held October 14, 1937, in the Engineering Societies Building, New York, N. Y. F. M. Farmer (A'02, F'13, director) was re-elected chairman, and D. Robert Yarnall was re-elected vice-chairman.

The executive committee is composed of these two, together with George E. Beggs, A. L. Queneau, and W. I. Slichter (A'00, F'12, national treasurer, member for life.)

O. E. Hovey was elected director, and John H. R. Arms was elected secretary.

These officers and the executive committee of The Engineering Foundation are elected by the Foundation board, from among its own members. The Engineering Foundation board is itself elected by the board of trustees of the United Engineering Trustees, Inc. The complete membership of the Engineering Foundation board for the year 1937–38 is as follows:

| Name | | Term Expires |
|---|---|---|
| *Four Trustees of U.E.T., Inc.* | | |
| A. L. Queneau | AIME | 1938 |
| D. Robert Yarnall | ASME | 1939 |
| H. P. Charlesworth | AIEE | 1939 |
| O. E. Hovey | ASCE | 1941 |
| *Eight Members Nominated by Founder Societies* | | |
| G. D. Barron | AIME | 1940 |
| G. E. Beggs | ASCE | 1939 |
| F. F. Colcord | AIME | 1938 |
| F. M. Farmer | AIEE | 1939 |
| W. H. Fulweiler | ASME | 1940 |
| Langdon Pearse | ASCE | 1938 |
| W. I. Slichter | AIEE | 1940 |
| A. E. White | ASME | 1939 |
| *Three Members-at-Large* | | |
| F. M. Becket | AIME | 1938 |
| J. V. N. Dorr | AIME | 1939 |
| E. R. Fish | ASME | 1939 |
| *Ex-officio, President, U.E.T., Inc.* | | |
| D. Robert Yarnall | | |

At the annual meeting members of the research procedure committee were appointed or re-appointed as follows:

D. R. Yarnall, *chairman*, representing The Engineering Foundation.

L. W. Chubb (A'09, F'21) director, Westinghouse Research Laboratories, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., representing AIEE.

F. F. Colcord, representing The Engineering Foundation.

W. H. Fulweiler, Wallingford, Pa., representing The American Society of Mechanical Engineers.

F. O. Scobey, senior irrigating engineer, United States Department of Agriculture, Berkeley, Calif., representing the American Society of Civil Engineers.

Sam Tour, Lucius Pitkin, Inc., New York, N. Y., representing American Institute of Mining and Metallurgical Engineers.

F. M. Farmer (A'02, F'13, director) *ex-officio.*

The personnel of other committees as appointed or re-appointed at this meeting is as follows:

IRON ALLOYS

G. B. Waterhouse, *chairman and director;* professor of metallurgy, Massachusetts Institute of Technology, Cambridge, Mass., representing American Institute of Mining and Metallurgical Engineers.

Director, National Bureau of Standards, Lyman J. Briggs, represented by Doctor J. G. Thompson, chief of section on chemical metallurgy, National Bureau of Standards, Washington, D. C.

Director, United States Bureau of Mines, J. W. Finch, represented by R. S. Dean, chief engineer, Metallurgical Division, Washington, D. C.

J. T. MacKenzie, metallurgist and chief chemist, American Cast Iron Pipe Company, Birmingham, Ala., representing American Foundrymen's Association.

John Johnston, director of research, United States Steel Corporation, Kearny, N. J., representing American Iron and Steel Institute.

Bradley Stoughton, dean of engineering, Lehigh University, Bethlehem, Pa., representing American Society for Metals.

Jerome Strauss, vice-president, Vanadium Corporation of America, Bridgeville, Pa., representing American Society for Testing Materials.

T. H. Wickenden, metallurgical engineer, International Nickel Company, New York, N. Y., representing The Society of Automotive Engineers.

J. H. Critchett, vice-president, Union Carbide and Carbon Research Laboratories, Inc., New York, N. Y., representing American Electrochemical Society.

Wilfred Sykes (A'09, F'14) assistant to the president, Inland Steel Company, Chicago, Ill., and a director; member-at-large.

F. T. Sisco, *editor.*

WELDING RESEARCH

C. A. Adams, (A'94, F'13, past-president, member for life) *chairman;* consulting engineer, Edward G. Budd Manufacturing Company, Philadelphia, Pa.

Everett Chapman, president, Lukenweld, Inc., Coatesville, Pa.

J. H. Critchett, vice-president, Union Carbide and Carbon Research Laboratories, Inc., New York, N. Y.

J. J. Crowe, engineer-in-charge of apparatus, research, and development department of Air Reduction Company, Jersey City, N. J.

## Table I. Summary of Annual Report of Finance Committee of U.E.T.

### Operation of Building

| | | |
|---|---|---|
| Operating revenue | | $ 159,636.82 |
| Less operating expenditures | | 135,291.79 |
| Net operating income before transfers to reserves | | 24,345.03 |

*A group of funds managed as one for convenience and economy in investment transactions.

A. S. Douglass, construction engineer, Detroit Edison Company, Detroit, Mich.

C. L. Eksergian, chief engineer, Budd Wheel Company, Detroit, Mich.

A. J. Ely, mechanical engineer, Standard Oil Development Company, Elizabeth, N. J.

H. M. Hobart (A'94, F'12, member for life) consulting engineer, General Electric Company, Schenectady, N. Y.

D. S. Jacobus (A'08, member for life) advisory engineer, The Babcock and Wilcox Company, New York, N. Y.

G. F. Jenks, colonel, Ordnance Department, United States Army, Washington, D. C.

Jonathan Jones, chief engineer, fabricated steel construction, Bethlehem Steel Company, Bethlehem, Pa.

P. G. Lang, Jr., engineer of bridges, Baltimore and Ohio Railroad, Baltimore, Md.

F. T. Llewellyn, research engineer, United States Steel Corporation, New York, N. Y.

Aubrey Weymouth, vice-president and chief engineer, Post and McCord, Inc., New York, N. Y. (Alternate for Jonathan Jones.)

William Spraragen (A'17, M'20) *secretary*, technical secretary and editor, New York, N. Y.

BARODYNAMIC RESEARCH: ADVISORY COMMITTEE

H. N. Eavenson, mining engineer, Pittsburgh, Pa.

H. G. Moulton, consulting mining engineer, New York, N. Y.

J. W. Finch, director, United States Bureau of Mines, Washington, D. C.

Chairman Farmer is Foundation's representative on the executive committee of National Research Council.

## Annual Report Issued by United Engineering Trustees, Inc.

The annual report of United Engineering Trustees, Inc., for the year ending September 30, 1937, has been submitted by G. L. Knight (A'11, F'17), president. The year showed reasonable stability in finances, full occupancy of the Engineering Societies Building, an increasing use of meeting halls, and improvement in the protection of property including resumption of contributions to the depreciation and renewal fund which had by necessity been withheld since 1932. Engineering Societies Building in its thirty-first year of activity remains in good physical condition with a minimum of repairs and maintenance expense. Minor improvements have been made in certain meeting-hall facilities. The American Institute of Chemical Engineers now has made its headquarters in the Engineering Societies Building.

The depreciation and renewal fund additions of $12,000 a year ceased in 1932 in order to lighten the building operating assessment against the societies at a time when the societies' income suffered from lowered volume of membership fees. During the year just closed, $15,000 has been added to the fund, the value of which is shown to be $352,411.96 against a building held at $1,447,793.92. A summary of the report of the U.E.T. finance committee is given in table I.

A new edition of history, charter, and by-laws of the corporation, the first since 1931, was issued just prior to the close of the fiscal year, and gives much of historical and legal interest not only to trustees and members of the Founder Societies, but also to any person who may wish to make a gift or bequest to the corporation or its departments for the advancement of science and engineering.

## Annual Report Issued by Engineering Foundation

The annual report of the Engineering Foundation for the year ending September 30, 1937, has been submitted by F. M. Farmer (A'02, F'13, director) chairman of the Foundation board. Chairman Farmer conducted the affairs of the Foundation during the year with the assistance of John H. R. Arms, secretary of United Engineering Trustees, Inc., following the death on March 14, 1937, of Doctor Alfred D. Flinn, secretary and director of the Foundation since 1917.

A summary of the capital fund of the Engineering Foundation and a condensed financial statement follows:

**Capital Funds**

| | |
|---|---|
| Endowment, total book value on September 30, 1937 | $872,000 |
| E. H. McHenry bequest, in hands of executors until decease of 2 life beneficiaries, appraised at probate of will in 1931, approximately | 400,000 |
| Fifth Swasey gift | 89,102 |

The capital funds are held and administered by United Engineering Trustees, Inc. The net income from endowment was $36,596.78 for the fiscal year ended September 30, 1937. The Foundation board has discretion in use of income. For many of the enterprises which the Foundation has aided, large contributions of money, services, and materials have been obtained from others.

**Expendable Resources**

| | | |
|---|---|---|
| Balance on October 1, 1936 | | $17,798.93 |
| Receipts | | |
| Income from endowment | $36,596.78 | |
| Income from minor items | 666.44 | 37,263.22 |
| Total resources | | $55,062.15 |
| **Disbursements** | | |
| Research projects | $22,134.28 | |
| Promotion of research and administrative expenses | 8,572.76 | |
| Total for furtherance and support of research | | 30,707.04 |
| Balance on October 1, 1937 | | $24,355.11 |

Money "contributions" from organizations and individuals, for specific activities, passed through the Foundation's accounts from its organization to September 30, 1937, totaled $282,851.60.

During the year ending September 30, 1937, the Foundation aided the following activities:

**Soil Mechanics and Foundations Division** (ASCE, $2,000). The following studies have been completed, or are under way:

(*a*) Settlement of structures. Progress report in the September 1937 ASCE *Proceedings*.

(*b*) Internal earth pressures. Studies have been made principally in New York City and Detroit. Report prepared and now before the publications committee of ASCE.

(*c*) Observed settlement of structures in Egypt. A report is being prepared.

(*d*) Properties of clay-type soils. Many thousands of tests have made made during the year but the program is not yet completed.

(*e*) Lateral stability of sheeting and piles. Some preliminary results have been published.

(*f*) Properties of "quick sands." Investigation just being started.

(*g*) Stability of earth dams subject to seepage. A series of tests is now under way.

(*h*) Problem of sand boils in connection with upward flow of water through soils. A series of tests is under way.

(*i*) Stability of earth banks subject to seepage. Data are being collected.

**Hydraulic Researches** (ASCE, $1,500). The following projects have been actively pursued during the year:

(*a*) Traveling waves on steep slopes. Studies of waves on a traveling belt through a glass-sided flume; 2 graduate theses have been written.

(*b*) Curves in open channels. Studies including motion pictures have been made with channels set up in Pyralin with the flow around a 180-degree bend.

(*c*) Phenomena of intersecting streams. After preliminary work with small metal flumes, square flumes have been constructed of Pyralin, experiments have been run with branch circuits at various angles, and studies made with water flowing in both directions. A thesis and a report have been prepared on the data obtained to date.

(*d*) Conversion of kinetic to potential energy. Library research and laboratory experiments being simultaneously conducted.

(*e*) Sedimentation at the confluence of rivers. A channel 12 by 24 inches and 65 feet long has been set up with a tributary channel and facilities have been provided for feeding sand to both flumes independently, and for varying the angle of convergence and the slope of the flumes.

**Alloys of Iron** (AIME, $5,000). This project, a critical compilation of the existing information on the alloys of iron, has been under way for several years. During this year 2 additional monographs were published, the total to date now being 9. Five chapters have been prepared for the tenth volume "The Alloys of Iron and Nickel—Volume I." A refinancing campaign carried on by the director of this project has resulted in subscriptions which with continued support by the Foundation at the present rate, will apparently finance this project to completion.

**Barodynamic Researches** (AIME, $2,500). Studies have been made of the following:

(*a*) Stress distribution in mine pillars and roofs. These studies are being made with the aid of the centrifugal photoelastic process previously developed in connection with this project.

(*b*) Methods of overcoming rock burst in deep mines.

(*c*) Development of artificial mine supports.

(*d*) The development of apparatus for the determination of pressure in loose materials.

A paper entitled "Modern Methods of Attacking Mining Problems," a direct result of the work on this project, was presented at the February 1937 annual meeting of AIME. It is expected that publication of information resulting from the above activities will be made during the coming year.

**Cutting Fluids** (ASME, $750). Experimental work completed on monel metal and reported in a paper in the November 1936 issue of ASME *Transactions*. Work being conducted on SAE 2345 steel.

**Critical Pressure Steam Boilers** (ASME, $850). This project has been under way for some time, the present program being the reaction between steam and metals at high temperatures. Apparatus is being built to test simultaneously 7 different tube materials.

**Fluid Meters** (ASME, $900). The present experimental program is on flow nozzles, an investigation which has been under way for some time, and is expected to require 3 years to complete. Articles concerning

this study have appeared in several technical journals.

**Strength of Gear Teeth** (ASME, $700). Twelve test runs have been made on a special surface fatigue testing machine. A series of reports on these tests of surface fatigue being prepared for publication.

**Lubrication** (ASME, $400). This project under a special research committee has included the compilation of a bibliography on lubrication started some time ago, a study of the problem of viscosity of lubricants under pressure, and investigation of increased viscosity under high pressure in bearing oil films. Two papers have been presented by members of the committee during the year. An extensive survey of lubrication research throughout the United States is being made.

**Effect of Temperature on the Properties of Metals** (ASME, $500). This extensive project, which has been under way for some years under the direction of a joint committee, the Foundation's contribution to which is a very small amount, was reorganized during the year, but a total of 9 research projects, either new or already under way, were prosecuted during the year.

**Stability of Impregnated Paper Insulation** (AIEE, $2,000). This project only got under way in 1936 under a supervisory committee designated by AIEE. Some time was spent in overhauling and improving equipment utilized on previous work. Certain preliminary test experiments involving a comparative study of a new procedure and the procedure previously used are nearly completed. Upon completion, the normal program, namely, the determination of the influence of the density and other physical properties of the paper on the electrical properties, the stability, and the life of impregnated paper insulation, will be started and will progress at a steady rate.

**Welding Research** (AIEE and AWS, $5,939). This project is very active under a large representative committee. The work is being carried on in 3 subdivisions, namely, fundamental research, industrial research, and literature. Each division has a record of important accomplishments during the year. A total of 32 reports comprising 368 printed pages were published during the year. These reports appeared in a supplement of the *Welding Journal*.

**Engineers Council for Professional Development** ($3,450). The death of General R. I. Rees has interfered with the carrying on of the work at rate contemplated; nevertheless much progress has been made under the chairmanship of Professor Chas. F. Scott (A'92, F'25, HM'29, past-president). The "accrediting schools" project has been highly successful so that during the year the perplexing problem of accrediting engineering education has been definitely solved. The total degree-granting schools that have been inspected to date is 134. Some of the Foundation funds were used for the general overhead expenses of this project but the cost of activity itself is self-liquidating from the fees paid by the schools, which to date have been something like $30,000. A study of the "evaluation of professional qualifications" is still under way. A study has been made of certain "aptitude tests" in 12 institutions which has confirmed previous reports that lack of schooling essential to engineering can be detected by these tests.

**Personnel Research Federation** ($1,200). A study of "Problems Incident to Engineering Advances" was made during the year and the results published in the *Personnel Journal*. The Federation considers that the extensive responses to these reports fully justify the investigation.

**Plastic Flow of Concrete** (University of California, $900). This investigation has been under way since 1926, and numerous reports have been issued to date, the most recent being a paper entitled "Plastic Flow and Volume Changes of Concrete" presented at the 1937 annual meeting of the American Society for Testing Materials. These later investigations included the studies to determine

(1) Effect of water-cement ratio and aggregate-cement ratio upon plastic flow.

(2) Effect of fineness and composition of cement upon plastic flow.

(3) Plastic flow of concrete in tension and in compression.

(4) Fiber strains in plain concrete beams under constant sustained bending moment.

(5) Stresses developed in large concrete cylinders under conditions simulating those occurring in mass concrete.

Detailed reports on the foregoing various projects are on file in the Foundation office, and show a large number of specific problems over a wide range, rather than a small number of elaborate problems. Further information on the Foundation and its activities may be obtained from the Foundation office, 29 West 39th Street, New York, N. Y.

## Annual Report Issued by Engineering Societies' Library

The annual report of the Engineering Societies' Library, containing information on the use of the library, its finances, and acquisitions, for the year ending September 30, 1937, has been submitted by Doctor Harrison W. Craver, director.

The number of readers was 26,750. In addition, 10,227 nonvisitors were supplied with information and material in various ways: 82 by the loan of 90 books, 112 by special bibliographies, 113 by translations, 2,374 by making 19,535 photocopies, 2,962 by letters, and 4,584 by telephone. Through all these methods, 36,977 persons used the library. In the previous year the library was used by 37,586 persons; 26,784 visitors and 10,812 nonvisitors. The number of users has thus remained practically constant, and the ratio of nonvisitors to visitors (2 to 5) has also remained the same.

Gifts and purchases during the year amounted to 11,003 pieces, of which 6,623 were new to the collection and were added to it. Sixty-seven volumes were added to the loan collection to meet requests from members, and the remaining items were given to other institutions or placed in the duplicate collection for sale or exchange. The sales of duplicates amounted to $431.50. Current issues of 1,416 periodicals were received, and 571 books, worth approximately $2,000, were received for review.

The gifts numbered 9,641 items; among them was that of Colonel W. J. Wilgus who presented his valuable library to the societies' library and the New York Public Library. Under an arrangement for the division of the collection planned by Colonel Wilgus and the directors of the 2 libraries, the societies' library received about 950 volumes and 255 cases of manuscript reports, etc., including all of the collection that dealt with engineering and that was not already on its shelves. A valuable collection of pamphlets by the late Frank J. Sprague (A'87, F'12, past-president) was presented by Mrs. Sprague. Other gifts were received from the *Engineering News Record*, the Perth Amboy Public Library, W. C. Huber, C. T. Hutchinson, Mrs. I. A. Ettlinger, Interborough Rapid Transit Company, Ralph Modjeski, J. L. Nicholson, George Orrok, F. F. Sharpless, and Mygren Werner, Inc.

A continuation of his gift by W. F. Barstow (A'94, F'12, Life Member) has made possible the restoration and rebinding of additional items in the collection of rare books.

On October 1, 1936, the library contained 138,742 volumes, 7,246 maps, and 4,298 manuscript bibliographies. During the year 184 volumes and 40 maps were withdrawn, and 2,734 volumes, 124 maps, and 64 bibliographies were added, bringing the total at the end to 141,292 volumes, 7,330 maps, and 4,362 searches. In addition, 3,701 pamphlets were added to volumes previously counted. The lending collection contained 660 volumes at the end of the year, and approximately 10,000 duplicate volumes and pamphlets were in stock. All new publications have been catalogued when received and made available at once. Cataloging is well abreast of receipts and there is no uncatalogued material except some recent gifts, which are being handled as rapidly as possible.

Substantial progress has been made on the periodical index, which is intended to provide a minutely classified guide to the important periodical literature of engineering. Over 20,000 references were added to the file, which now contains 187,000 references to material published during the past 10 years. The index is becoming increasingly popular with readers, and it is a matter of regret that funds are not available for its extension. More indexers are needed, as the present staff cannot cope with all that is being published.

Early in 1937, a microfilm copy of the library catalogue was made and deposited in a bank vault for safekeeping. From this film, duplicate card catalogues can be made at any time by a simple photographic process. Possession of the film has made possible an important reduction in the amount of insurance carried and so effected a continual annual saving of expense.

The budget for general operations was $46,700. Of this sum, $33,000 was appropriated by the Founder Societies, as follows:

| | |
|---|---|
| American Society of Civil Engineers | $8,890.90 |
| American Institute of Mining and Metallurgical Engineers | 6,921.40 |
| American Society of Mechanical Engineers | 8,399.50 |
| American Institute of Electrical Engineers | 8,788.20 |

Expenditures from the appropriation amounted to $42,944.15 of which $8,578.86 was spent for books and other equipment which increased the assets of the library. The service bureau received $7,887.08 and expended $6,581.87.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or reject them entirely.

ALL letters submitted for consideration should be the original typewritten copy, double spaced. Any illustrations submitted should be in duplicate, one copy to be an inked drawing but without lettering, and other to be lettered. Captions should be furnished for all illustrations.

STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Rotor Flux Locus Concept of Single-Phase Induction Motor

*To the Editor:*

In the discussion (*EE, Aug. 1937, p. 1028–30*), of C. T. Button's paper "A Suggested Rotor Flux Locus Concept of Single-Phase Induction-Motor Operation," there was no intention of disagreement and any seeming disagreement is doubtless due to the inability of clearly expressing thoughts in words.

Mr. Button is correct in saying that the condition wherein the rotor flux may be considered as substantially constant along a diameter of the rotor is at or near synchronism. However, this condition was mentioned in the second paragraph and included throughout the comments.

He also states that the "pulsating component in the quadrature rotor axis" is neglected. While this statement is indefinite, it is assumed that it refers to the quadrature flux component. A careful reading of the comments will show that the quadrature flux is accounted for by the double-frequency flux-sustaining currents and the rotation of the rotor. In the assumed case where the rotor is held stationary and the field excited by rectified single-phase current, the factor of field rotation is eliminated and the flux acts only in one fixed direction, so that in this case there is no quadrature space relation, but the flux that is sustained by the double-frequency rotor currents while the primary magnetizing force goes through zero is the quadrature time flux.

The expression "after the rotor flux is once established" was merely intended to exclude the transient conditions as the rotor comes up to speed.

Considering the single-phase motor in the form of a stationary squirrel cage in a field excited by rectified single-phase current is the same method as used in considering a polyphase motor in the form of a squirrel cage in a d-c or constant field. It eliminates the factor of field rotation in both cases.

Mr. Button states that the conditions of coils *A* and *B* are transitory. This is true under slip conditions. However, this assumption of the two coils at right angles was used only in connection with synchronous conditions where they are not transitory. The comments clearly stated that in the practical motor under slip conditions these two sets of currents, the slip or torque currents of slip frequency and the flux sustaining currents of double frequency, less slip, are superimposed, and that the positions of the rotor conductors are constantly shifting from the transformer to the speed condition and vice versa. This action produces the characteristic single-phase rotor current form of one wave of slip frequency with another of double frequency less slip superimposed.

The expression "tendency to keep in synchronism" may be somewhat misleading. However, it does not indicate that the rotor actually attains synchronism, but that there is a tendency in that direction, a well-known characteristic of squirrel-cage motors.

The term "torque" was used in the sense of the torque produced by the electrical reactions between the field and rotor. Unless we eliminate mechanical rotation and reduce to stationary conditions as outlined by holding the rotor stationary and rectifying the single-phase exciting current, there is a negative torque due to friction, windage, etc., but this torque is not pulsating. Pulsating negative torque is only produced above synchronism.

The terms "speed voltage" and "transformer voltage" were used to indicate their source. A speed voltage involves a transformation between electrical and mechanical forces while a transformer voltage involves a transformation between electrical forces.

As Mr. Button states, the reactions under slip conditions are rather complex. It was intended to confine the argument more particularly to synchronous conditions and show how at synchronism, the double-frequency rotor currents maintain the flux approximately constant along a fixed rotor diameter, so that a rotary field is developed by the mechanical rotation of the sustained rotor flux. Other characteristics of the single-phase squirrel-cage motor that are explained by this method were mentioned, but space would not permit taking them up in detail.

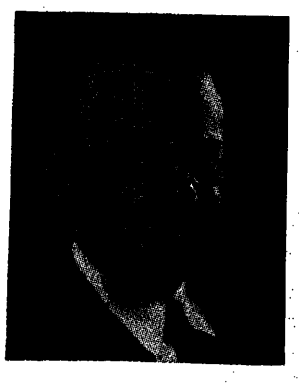
Very truly yours,
EDWARD BRETCH (M'19)
President, The Advance Electric Company, St. Louis, Mo.

# Personal Items

A. P-T. SAH (A'35, M'36) professor of physics, Tsing Hua University, Peiping, China, recently was appointed president of the National University of Amoy, Amoy, China. Doctor Sah, who formerly served as visiting professor on the electrical engineering faculties of both The Ohio State University and the Massachusetts Institute of Technology, was born July 24, 1902, at Foochow, China, and after receiving the degree of bachelor of arts at Stanford University in 1924, enrolled in the electrical engineering school of Worcester Polytechnic Institute, where he received the degree of electrical engineer (1925) and doctor of science (1927). For one year after his graduation in 1927 he was affiliated with the Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., following which be became chief engineer of the China Radio Corporation, Tientsin. In 1928 he was appointed assistant professor of electrical engineering and physics at Tsing Hua University and in the following year he received his full professorship. In 1936 Doctor Sah returned to the United States as visiting professor of electrical engineering at The Ohio State University and Massachusetts Institute of Technology, and during his stay presented 2 papers on the engineering application of dyadics at the Institute's 1937 winter convention. Since 1935 Doctor Sah has served as a member of the Chinese National Electrotechnical Committee, affiliated with the International Electrotechnical Commission. He is a member of the Chinese Engineering Society, Chinese Science Society, Chinese Physical Society, and the Chinese Institute of Electrical Engineering.

A. P-T. SAH

G. M. L. SOMMERMAN (A'31, M'37) research engineer for the American Steel & Wire Company, Worcester, Mass., has been awarded the Alfred Noble Prize for 1937, as reported elsewhere in this issue. The award was made for his paper "Properties of Saturants for Paper-Insulated Cables," which was published in the May 1937 issue of ELECTRICAL ENGINEERING, pages 566–76, and presented at the AIEE 1937 summer

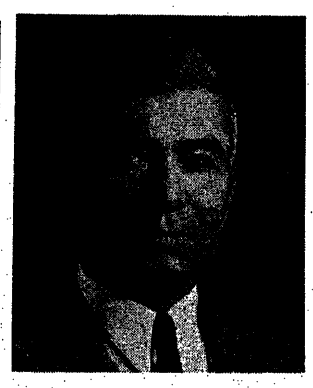


convention, Milwaukee, Wis., June 21–25. Doctor Sommerman was born July 2, 1909, at Baltimore, Md., and received the degrees of bachelor of engineering (1929) and doctor of engineering (1933) at The Johns Hopkins University. Following his graduation in 1929 he became a research assistant at that institution, devoting his attention to investigations sponsored by the former National Electric Light Association, and in the following year enrolled in the graduate school of electrical engineering. In 1931 he became an assistant physicist for the Consolidated Gas, Electric Light, and Power Company of Baltimore, and in 1934 joined the research engineering staff of the American Steel & Wire Company, where he has been in charge of fundamental researches on properties of materials for use in high-voltage cables. Doctor Sommerman is a member of the Institute's committee on research and was a member of the committee on instruments and measurements from 1934 until 1937. He has made many contributions to the technical literature on dielectrics, and has been an active member of the committee on electrical insulation of the division of engineering and industrial research of the National Research Council. He is a member of the American Physical Society, American Association for the Advancement of Science, American Society for Testing Materials, Sigma Xi, and Tau Beta Pi.

S. A. TUCKER (A'28) division engineer, Brooklyn Edison Company, Inc., Brooklyn, N. Y., recently became associate editor of *Power* a periodical published by the McGraw-Hill Publishing Company, New York, N. Y. Mr. Tucker was born October 11, 1905, at New Britain, Conn., and is an electrical engineering graduate of Yale University. Soon after his graduation he became associated with the Brooklyn Edison Company as a cadet engineer, and was associated with that company for more than 10 years.

A. J. ALLEN (M'27) operating vice-president of the Ohio Bell Telephone Company, Cleveland, recently was made president of the Cincinnati and Suburban Bell Telephone Company, Cincinnati, Ohio. Mr. Allen was born April 27, 1881, at Peoria, N. Y., and attended Geneseo State Normal School and Williams College. In 1907 he became associated with the Central District Telegraph Company, Pittsburgh, Pa., as a traffic assistant, later becoming division supervisor of traffic before leaving that company to join the engineering department of the American Telephone and Telegraph Company, New York, N. Y., in 1910. For several years his work with the American Telephone and Telegraph Company was concerned with local operating and engineering problems, but later he became a traffic engineer and in 1929 was made an assistant vice-president of the company. In the following year he was transferred to Cleveland as operating vice-president of the Ohio Bell Telephone Company.

T. H. HOGG (M'31) chief hydraulic engineer of the Hydro-Electric Power Commission of Ontario, Toronto, has been appointed chairman of the Commission. Mr. Hogg was born April 20, 1884, at Chippawa, Ontario, and received the degrees of bachelor of applied science, civil engineer, and doctor of engineering at Toronto University. In 1908 he became a member of the designing department of the Ontario Power Company, remaining there until 1911, when he became editor of *Canadian Engineer*. His affiliation with the Hydro-Electric Power Commission began in 1913, when he was appointed assistant hydraulic engineer. Doctor Hogg held that position until he was appointed chief hydraulic engineer in 1921. Since 1926 he has served as a consulting engineer for the government of the Dominion of Canada, the Province of Ontario, and for several local power companies.



S. A. CANARIIS (A'25, M'27) assistant power engineer, Bureau of Water, Department of Public Works of the City of Pittsburgh, Pa., recently was appointed water works electrification engineer for the industrial department of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. Born in Odense, Denmark, in 1893, Mr. Canariis received his formal technical education at the Polytechnical School of Odense, graduating in 1915. In 1922 he came to the United States, and was employed by several companies in various capacities before being appointed senior engineer of the commercial engineering division of the Duquesne Light Company, Pittsburgh, Pa., in 1926. Mr. Canariis became assistant power engineer for the Bureau of Water of the City of Pittsburgh in 1931.

A. J. ALLEN

G. M. L. SOMMERMAN

T. H. HOGG

R. M. BAKER (A'35) research engineer, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has been appointed to the faculty of the Kansas State College of Agriculture and Applied Science, as an instructor in electrical engineering. Mr. Baker, a native (1903) of College Station, Texas, received the degree of bachelor of science in electrical engineering at the University of Texas in 1926, and the degree of master of science in electrical engineering at the University of Pittsburgh in 1931. Since 1928 he has been employed continuously in the research laboratories of the Westinghouse company, where he has been occupied chiefly in a study of electrical sliding contacts and related problems. During 1932–33 he studied in the Technische Hochschule of Charlottenburg, Germany, and was associated with the Siemens Research Laboratories in Berlin. Mr. Baker has presented several papers before the Institute.

ARTHUR SIMON (A'03, F'13) consulting electrical engineer for the Cutler-Hammer Co., Milwaukee, Wis., has established his own consulting engineering firm, with offices in Milwaukee. Doctor Simon was born in Ebersheim, Germany, May 21, 1881, was educated in the public schools of Germany, and later attended the Technical University of Darmstadt, from which he received a diploma of engineering in 1902. He came to the United States in 1903 when he entered the employ of Cutler-Hammer Company as an electrical engineer. In 1905 he was placed in charge of a-c engineering, and in 1921 was appointed consulting engineer to the company. He served as a member of the Institute's committee on power transmission and distribution, from 1923 until 1925. Doctor Simon will retain his connection with the Cutler-Hammer Company.

J. H. MANNING (M'14) president, Stone and Webster Engineering Corporation, New York, N. Y., has retired from active service. Born October 1, 1883 at Fall River, Mass., Mr. Manning was graduated from Worcester Polytechnic Institute with the degree of bachelor of science in civil engineering in 1906 before becoming associated with the consulting engineering firm of Hugh L. Cooper, New York, N. Y., as a draftsman. He remained with that organization until 1910, when he joined the staff of the Stone and Webster Engineering Corporation at Boston, Mass. He was superintendent of construction on many of the Stone and Webster projects throughout the United States, and has been associated with the engineering activities of that organization continuously for 27 years. Mr. Manning is a member of the American Society of Civil Engineers.

S. L. HENDERSON (A'12, M'34) section engineer for the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has been promoted to the position of district engineer, with offices at New York, N. Y. A native of Boston, Mass. (1883), Mr. Henderson received the degree of bache-

lor of science in electrical engineering at Massachusetts Institute of Technology in 1910, following which he entered the test course of the Westinghouse Company. In 1913 he was appointed design engineer and successively became division engineer and section engineer. He was a member of the Institute's committee on electrical machinery from 1928 until 1935 (chairman 1932–34) and a member of the technical program committee from 1932 until 1934. At present Mr. Henderson is a member of the sectional committee on rotating machinery of the American Standards Association.

R. C. MASON (A'26) who has been for several years a research engineer for the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., recently has become associated with the Physisch Laboratorium, Utrecht, Netherlands. Mr. Mason is a native (1903) of Bentonville, Arkansas, and an electrical engineering graduate of the University of Arkansas (1924). After graduating from the student training course of the Westinghouse Company, he became an engineer in the materials and process engineering department in 1925, but later was transferred to the research laboratories. Mr. Mason was a member of the electrophysics (now basic sciences) committee from 1933 until 1937 (chairman 1936–37).

W. A. NICHOLS (A'37) since 1931 an engineer in the special products department of the Northern Electric Company, Ltd. Montreal, Que., Canada, recently became associated with the Canadian Broadcasting Corporation as chief engineer of radio station CBL at Hornby, Ontario. Mr. Nichols, a graduate (1928) of the University of Toronto, formerly was associated with Canadian National Telegraphs, and with the Northern Electric Company, where much of his work was concerned with sound equipment.

J. H. IRWIN (A'20) who has been a cable specialty salesman in the Chicago (Ill.) office of the Aluminum Company of America for the last 13 years recently was made manager of the company's Atlanta Ga. office. Mr. Irwin was born December 12, 1892, at Philadelphia, Pa., and was graduated from the University of Pennsylvania in 1915 with the degree of bachelor of science, immediately following which he joined the engineering sales staff of the Aluminum Company of America, with offices at Philadelphia, Pa.

E. W. CONROY (M'32) superintendent of light and power, Puget Sound Power and Light Company, Bremerton, Wash., has been transferred to the central district offices of the company at Seattle, Wash., and has been made assistant to the general superintendent of light and power. Mr. Conroy, a native of Helena, Mont., and an electrical engineering graduate of the University of Washington, has been associated with the Puget Sound Power and Light Company continuously since 1922.

G. W. THAXTON (M'36) formerly division engineering supervisor of the Rural Electrification Administration, Washington, D. C., has become electrical engineer for the Chase Brass and Copper Company, Inc., and the Kennecott Wire and Cable Company, New Orleans, La. Prior to his affiliation with the Rural Electrification Commission, Mr. Thaxton was division engineer of the Tennessee Valley Authority at Tupelo, Miss.

E. L. MORELAND (A'11, F'21) partner in the firm of Jackson and Moreland, Boston, Mass., and head of the department of electrical engineering of Massachusetts Institute of Technology, Cambridge, has been appointed to represent the Institute as alternate on the electrical standards committee of the American Standards Association. Professor Moreland is also Institute representative on the standards council of the American Standards Association.

FREDERICK BEDELL (A'91, F'26, past vice-president, member for life) recently retired from his position as professor of physics at Cornell University, Ithaca, N. Y., and will become professor emeritus. Doctor Bedell will continue to do research work at the University and in the R. C. Burt Scientific Laboratories, Pasadena, Calif., where he expects to spend the next few months.

H. S. DIXON (A'35) who has been an assistant engineer, Reclamation District No. 108, Knights Landing, Calif., recently became a member of the electrical engineering staff of Purdue University, Lafayette, Ind. A native (1910) of Woodland, Calif., Mr. Dixon received the degree of bachelor of arts (1931) and the degree of electrical engineer (1935) at Stanford University. He is a member of Tau Beta Pi.

W. M. LEEDS (A'32) electrical engineer for the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., recently awarded a B. G. Lamme scholarship by the Westinghouse company, has been granted a year's leave of absence to pursue graduate work at Massachusetts Institute of Technology, following which he will return to the switchgear engineering department of the company.

F. V. MAGALHAES (A'07, F'19) executive assistant to the president, Consolidated Edison Company of New York, Inc., New York, N. Y., has been appointed to serve as the Institute's representative on the committee on low-voltage hazards of the National Safety Council, and on the electrical committee of the National Fire Protection Association. Mr. Magalhaes is chairman of the Institute's board of examiners.

J. D. ROSS (A'08, F'12) superintendent of lighting, City of Seattle, Wash., and a former member of the United States Securities and Exchange Commission, has been appointed administrator of the Bonneville power project. Mr. Ross has been associated with the city lighting department of Seattle for 30 years, 26 of which have been as superintendent.

E. A. BALDWIN (A'07) vice-president and general European manager of the International General Electric Company, Paris, France, recently was made an officer of the Legion of Honor in recognition of his many services to France. Mr. Baldwin has been associated with the General Electric Company since 1896, and has been in the foreign department of the company since 1899.

O. F. ALLEN (A'10, F'24) consulting engineer, New York, N. Y., recently resigned from his position with the Public Works Administration in New York, to devote his entire time to his consulting engineering practice. He continues as managing director of Martin Motors, Inc., and as secretary and director of American Rezo, Inc.

C. F. HARDING (A'06, F'14, vice-president) head of the school of electrical engineering and director of the electrical laboratories of Purdue University, Lafayette, Ind., has been appointed to serve as the Institute's representative on the American Engineering Council assembly for the calendar year 1938.

W. H. BLISS (A'30) formerly an instructor in electrical engineering at the University of Maine, Orono, recently became a communications engineer for RCA Communications, Inc., New York, N. Y., where he is doing experimental work on radio facsimile transmissions.

R. A. SCHLEGEL (A'36) who has been colliery electrician for the Philadelphia and Reading Coal and Iron Company, Mahanoy City, Pa., recently became a service engineer with the Brown Instrument Company Industrial Division of the Minneapolis Honeywell Regulator Company, Philadelphia, Pa.

V. M. MONTSINGER (A'14, F'29) research engineer, General Electric Company, Pittsfield, Mass., has been appointed to serve as the Institute's representative on the electrical standards committee of the American Standards Association. Mr. Montsinger is chairman of the Institute's committee on standards.

W. M. BAUER (A'29, M'36) since 1929 an instructor in electrical engineering at Northwestern University, Evanston, Ill., now is a part-time assistant in electrical engineering at Harvard University, Cambridge, Mass., where he is enrolled in the graduate school as a candidate for a doctorate degree.

H. M. WITHEROW (A'28, M'36) designing engineer General Electric Company, Fort Wayne, Ind., has been transferred to the design department of the General Electric Company, Lynn, Mass. Mr. Witherow is a past chairman (1935–36) of the AIEE Fort Wayne Section.

MACKLEN KLEIMAN (A'37) assistant engineer, Thompson Gibb Electric Welding Company, Lynn, Mass., recently became welding engineer for the Lycoming Division of the Aviation Manufacturing Corporation,

Williamsport, Pa. Mr. Kleiman is a member of the American Welding Society.

F. E. JOHNSON (A'13, F'31, director) dean of the college of engineering, University of Missouri, Columbia, has been appointed to serve as the Institute's representative on the Engineer's Council for Professional Development for the term 1937–40.

F. J. SAFFORD (A'35) who has been an assistant in the electrical engineering department of Columbia University, New York, N. Y., recently was appointed a research assistant in the department of electrical engineering at Massachusetts Institute of Technology, Cambridge.

L. F. MOREHOUSE (A'16, F'20) has been elected to full membership in the British Institution of Electrical Engineers. Doctor Morehouse is technical representative in Europe of the American Telephone and Telegraph Company and of Bell Telephone Laboratories, Inc., with offices in London.

F. M. FARMER (A'02, F'13, director) vice-president and chief engineer of the Electrical Testing Laboratories, New York, N. Y., has been appointed to serve the Institute as representative on the United Engineering Trustees, Inc., for the 4-year term beginning October 1937.

H. A. LARDNER (A'94, F'13, member for life) vice-president, The J. G. White Engineering Corporation, New York, N. Y., has been elected a vice-president of United Engineering Trustees, and also a trustee of that agency, representing the American Society of Mechanical Engineers.

WILLS MACLACHLAN (A'08, F'21, past vice-president) consulting electrical engineer, Toronto, Ont., Canada, has been appointed to serve the Institute as representative on the National Fire Waste Council. Mr. Maclachlan is chairman of the Institute's committee on safety.

DOUGLAS MONTGOMERY (A'26) has resigned from the Westinghouse Electric & Manufacturing Company, New York, N. Y., with which company he was a field engineer, to become an electrical draftsman for The Detroit Edison Company, Detroit, Michigan.

J. E. ZIPOND (A'23) who has been an assistant electrical engineer for the public works branch, United States Treasury Department, Washington, D. C., recently became associated with the Duquesne Light Company, Pittsburgh, Pa., as an electrical engineer.

J. W. GRAY (A'36) formerly a teaching fellow in the physics department of the University of Washington, Seattle, now is an instructor in the electrical engineering department of the University of Idaho, Moscow.

G. H. BLIESNER (A'35) until recently farm electrification agent for the Puget Sound Power and Light Company, Mount Vernon, Wash., now has become agricultural electrical engineer for the Yam Hill Electric Company, Newburg, Ore.

R. F. HAYS, JR. (A'36) formerly an instructor in the department of physics, Mississippi State College, State College, now is employed as a vapor lamp engineer by the Westinghouse Lamp Division at Bloomfield, N. J.

E. R. PAIGE (A'35) until recently an electrical engineering instructor at Cornell University, Ithaca, N. Y., has become affiliated with the engineering department of the Niagara Hudson Power Corporation, Buffalo, N. Y.

H. H. HENLINE (A'19, M'26, national secretary) has been appointed to serve as the Institute's representative on the standards council of the American Standards Association for the 3-year term beginning January 1, 1938.

ROY WILKINS (A'16, F'29) who has been an engineer for the K-P-F Electric Company, San Francisco, Calif., now is associated with the firm of George E. Honn, San Francisco. Mr. Wilkins has been a consulting engineer in that city for several years.

FRANK WOREL (A'29) who has been chief toll testman of the Michigan Bell Telephone Company, Ann Arbor, has been transferred to the Grand Rapids office of that company as an exchange repairman.

H. L. COLLINS (A'35) has resigned his position as chief engineer of the Invincible Vacuum Cleaner Manufacturing Co., Dover, Ohio, to become production engineer with the Knapp-Monarch Company, St. Louis, Mo.

GEORG KEINATH (M'37) director of the laboratories of Siemens and Halske, Berlin, Germany, recently came to the United States to establish consulting engineering offices at New York, N. Y.

K. H. BLACK (A'37) second lieutenant, U.S. Army Corps of Engineers, Fort Lawton, Seattle, Wash., now is employed in the meter department of the Puget Sound Power and Light Company, Seattle.

K. E. V. HALLAR (A'31) formerly assistant operating and maintenance engineer with the Husqvarna Vapenfabriks, Huskvarna, Sweden, now is with the Stone and Webster Engineering Corporation, Boston, Mass.

H. E. REED (A'32) formerly an electrical operator for the Maine Seaboard Paper Company, Bucksport, now is employed as an electrical tester for the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

C. V. POLING (A'27) formerly an electrical engineer in the Hawthorne works of the Western Electric Company, Inc., Chicago, Ill., has been appointed an assistant electrical engineer for the Tennessee Valley Authority, Knoxville, Tenn.

A. M. FLUKE (A'37) who has been a test engineer for the General Electric Company, Schenectady, N. Y., has been transferred to the Bridgeport, Conn., works of that company in the resistance welding engineering department.

R. A. TYLER (A'36) who has been assistant superintendent in the electric department of the Oklahoma Gas and Electric Company, Enid, has been transferred to the Oklahoma City offices of that company as service foreman.

J. R. EATON (A'27, M'35) until recently an engineer for the Consumer Power Company, Jackson, Mich., has enrolled in the graduate school of electrical engineering at the University of Wisconsin, Madison.

H. D. LARRABEE (A'06) operating superintendent of the Connecticut Light and Power Company, Norwich, Conn., has been transferred to the Willimantic offices of that company.

F. B. WESTON (A'33) who has been a draftsman for the General Electric Company, Bridgeport, Conn., now is a junior design engineer for M. H. Rhodes, Hartford, Conn.

G. K. WILLIAMS (A'34) until recently an electrical engineer at Cornell University, Ithaca, N. Y., now is employed in the inspection development laboratory of the Western Electric Company, Baltimore, Md.

H. R. WOODROW (A'12, F'23, past-director) vice-president of the consolidated Edison Company of New York, Inc., New York, N. Y., has been elected a vice-president of United Engineering Trustees.

## Obituary

ROBERT CALTHROP BROWN (A'03, member for life) vice-president of the Brazilian Tramway, Light, and Power Company, Barcelona Tramway, Light, and Power Company, Mexican Light and Power Company, Mexico Tramway Company, and Canadian and General Finance Company, Ltd., Toronto, Ont., Canada, died October 30, 1937. Mr. Brown, born June 1, 1866, at Medford, Mass., was graduated from Tufts College with the degree of bachelor of arts in 1888, and received the degree of electrical engineer in 1894. In 1889 he was employed by the Somerville Electric Light Company as lineman, but later in the same year entered the employ of the West End Street Railway Company, Boston, Mass., in its engineering department. In 1890 he was appointed assistant superintendent of electric power in the same company, which position he held for one year before resigning to take charge of the electrical work of the Brooklyn City Railroad, Brooklyn, N. Y., in 1891. In 1894 Mr. Brown became affiliated with the Montreal Street Railway Company as an electrical engineer, and from 1895 to 1898 was employed by the Halifax Tramway, Light, and Power Company as general manager. In 1899 he went to Brazil, where he remained until 1901 as general manager of the Sao Paulo Tramway, Light, and Power Company. From 1902 until 1905 he served as electrical engineer

with the Toronto and the Niagara River Power Company; in 1906 he was appointed managing director of the Mexican Tramways Company, Mexico City, and subsequently held numerous offices in Mexican and South American companies.

PHILIP PRICE BARTON (A'00, M'01, F'12, member for life) retired electrical engineer, Hartford, Conn., died September 3, 1937. Mr. Barton was born May 5, 1865, at Lock Haven, Pa., and was graduated from Cornell University with the degree of bachelor of philosophy in 1886; he then enrolled in the graduate school and was granted the degree of master of science in 1888, following which he was employed in the electrical department of the Cambria Iron Company, Johnstown, Pa. In the same year he became associated with the Allegheny County Light Company, Pittsburgh, Pa., but remained there only for a brief period before becoming a test engineer for the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., in 1889. Later he was transferred to the Chicago (Ill.) offices of that company as a construction engineer, and remained there until 1891, when he was employed in the office of the special agent of the Brush Electric Company, Pittsburgh, Pa., as engineer and salesman. After serving in a similar capacity in the Pittsburgh offices of the General Electric Company for a brief period, Mr. Barton was appointed assistant electrical superintendent of the Niagara Falls Power Company in 1899. Successively he became superintendent of operation, general manager, vice-president and general manager, serving concurrently as general manager of the Canadian Niagara Power Company, vice-president and general manager of the Niagara Junction Railway Company and the Niagara Development Company, and as director of the Bank of Niagara.

JAMES AQUILLA CORRELL (A'08, M'29) professor of electrical engineering, University of Texas, Austin, died October 30, 1937. Professor Correll was born in Wayne County, Ohio, May 4, 1883, and received the degrees of bachelor of science in mechanical engineering (1903) at Kansas State Agricultural College, bachelor of science in electrical engineering (1907) at Massachusetts Institute of Technology, and master of science in electrical engineering (1925) at the University of Texas. Following his graduation in 1903 he was appointed refrigeration engineer for the Louisiana Purchase Exposition at St. Louis, Mo., and following the close of the exposition, became assistant engineer for the Zeigler Coal Company, Zeigler, Ill. In 1907 he was apopinted to the faculty of the University of Texas as an instructor in electrical engineering, later becoming adjunct professor (1915), associate professor (1918), and professor of electrical engineering (1927). During the World War he was head of the engine division of the United States Government school of military aeronautics at the University of Texas. Professor Correll was co-author of a textbook on a-c circuits, and was a member of the Society for the Promotion of Engineering Education and the former National Electric Light Association.

ALBERT BENTON JUNKINS (M'24) contracting electrical engineer, Baltimore, Md., died in July 1937, according to word just received at Institute headquarters. Mr. Junkins was born in Baltimore February 12, 1894, attended Baltimore City College, and received the degree of bachelor of science in electrical engineering at The Johns Hopkins University in 1917. Following his graduation he became assistant to the power plant engineer of the Chesapeake and Potomac Telephone Company, Baltimore, but in the following year received a commission in the communication branch of the United States Army Air Corps, serving as an instructor in radio and telephone communication. In 1919 he returned to his former position with the Chesapeake and Potomac Telephone Co., but remained for only one year before becoming electrical engineer for the Union Ship Building Company, Baltimore. In 1921 Mr. Junkins became affiliated with Stone and Webster, Inc., as assistant to the electrical superintendent on the construction of the American Sugar Refinery, Baltimore, and upon completion of that project became electrical engineer for the newly organized company. After serving briefly as a construction engineer for the Electromechanical Company, Baltimore, he established his own electrical contracting business, and pursued it without interruption for more than 10 years.

# Membership

## Recommended for Transfer

The board of examiners at its meeting on November 18, 1937, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

**To Grade of Fellow**

Case, H. M., chief engineer, Long Island Lighting Company, New York, N. Y.
Hunt, L. F., protection engineer, Southern California Edison Company, Ltd., Los Angeles, Calif.
McKearin, J. P., chief engineer, Western Massachusetts Companies, Springfield, Mass.
Wooldridge, William J., manager, electric sheet sales, Allegheny Steel Company, Brackenridge, Pa.

4 to Grade of Fellow

**To Grade of Member**

Baker, T. S., chief engineer, communications division, Hearst Radio, Inc., New York, N. Y.
Bellows, K. F., division engineer, Consolidated Edison Company of New York, Inc., New York, N. Y.
Blakeslee, T. M., electrical engineer, Bureau of Power and Light, Los Angeles, Calif.
Burke, J. H., electrical engineer, The Scranton Electric Company, Scranton, Pa.
Craton, F. H., commercial engineer, General Electric Company, Erie, Pa.
Hapgood, K. E., assistant engineer of design and construction, Tennessee Valley Authority, Chattanooga, Tenn.
Hough, E. L., electrical engineer, Union Electric Company, St. Louis, Mo.
Keene, C. L., supervising engineer, Ocean Accident and Guarantee Corporation, New York, N. Y.
Leihy, C. W., editor, *Electric Light and Power*, Chicago, Ill.
Love, N. R., chief engineer, Denver Tramway Corporation, Denver, Colo.
McLean, C., assistant engineer, Northwestern Electric Company, Portland, Ore.
Scheering, W. S., substation engineer, Western Mass. Companies, Springfield, Mass.
Schlup, E. G., electrical engineer, The American Rolling Mill Co., Middletown, Ohio.

13 to Grade of Member

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the national secretary before December 31, 1937, or February 28, 1938, if the applicant resides outside of the United States or Canada.

Anderson, J. W., Metropolitan Water District of Southern California, Los Angeles, Calif.
Bagnall, V. B. (Member) American Telegraph and Telephone Company, New York, N. Y.
Bain, J. R., Dominion Sound Equipments, Ltd., Vancouver, B. C., Canada.
Baker, B. P., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Bloodworth, E. W., Wilson Dam, Ala.
Bloxam, E. L., Duke Power Company, Salisbury, N. C.
Borland, E. E., Smith Milligan Electric Company, Tulsa, Okla.
Breon, K. H., Pennsylvania Power & Light Company, Williamsport, Pa.
Brown, F. H., Copperweld Steel Company, New York, N. Y.
Browne, A. A., Westinghouse Electric & Manufacturing Company, Portland, Ore.
Bulliet, L. J., W. F., and John Barnes Company, Rockford, Ill.
Cain, D. E., General Electric Company, St. Louis, Mo.
Caplan, R. S., Gulf Refining Company, Houston, Texas.
Cartmell, A. W., Municipal Light and Power Department, City of Pasadena, Calif.
Clayton, M. B., Tennessee Valley Authority, Wilson Dam, Ala.
Colby, B. H., General Electric Company, Pittsfield, Mass.
Cook, V. M., Consolidated Edison Company of New York, Inc., New York, N. Y.
Davenport, H. H., Southwestern Bell Telephone, Company, San Antonio, Texas.
Dillon, H. W., Southern Pacific Lines, Houston, Texas.
Doumaux, A. R., General Electric Company, New York, N. Y.
Elliott, R. M., Pacific Telephone and Telegraph Company, San Francisco, Calif.
Evans, K., Canadian Westinghouse Company, Hamilton, Ont., Canada.
Fay, F. H. (Member) American Telephone and Telegraph Company, New York, N. Y.
Fisher, H. J., Bell Telephone Laboratories, Incorporated, New York, N. Y.
Galassini, J. P., Commonwealth Edison Company, Chicago, Ill.
Garman, G. W., General Electric Company, Schenectady, N. Y.
Glenny, W. W., Reliance Electric & Engineering Company, Cleveland, Ohio.
Gower, A. G., Jr., (Member) Westinghouse Electric and Manufacturing Company, Boston, Mass.
Grandi, L. L., Agriculture and Mining College of Texas, College Station.
Hannah, E. I., Maydwell & Hartzell, Inc., Los Angeles, Calif.
Harker, D. C., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Hebbard, R. E., Interborough Rapid Transit Company, New York, N. Y.
Hawekotte, R. M., Bell Telephone Laboratories Incorporated, New York, N. Y.
Hochstetter, P. E., United American Bosch Corporation, Springfield, Mass.
Huffstutter, J. W., Westinghouse Electric & Manufacturing Company, Sharon, Pa.
Hull, R. (Member) Delco-Remy Corporation, Anderson, Ind.
Jimenez-Michelena, L. G., Massachusetts Institute of Technology, Cambridge.
Johnson, J. S., Stone and Webster Engineering Corporation, Hartford, Conn.
Kerr, T. B., Quincy Electric Light and Power Company, Quincy, Mass.
Klingensmith, J. A., Electric Storage Battery Company, Washington, D. C.
Kotchevar, J. F., Janette Manufacturing Company, Chicago, Ill.
Kurth, H. L. R. (Member) Boston Edison Company, Boston, Mass.
Lachicotte, F. W. (Member) Duke Power Company, Charlotte, N. C.
Lachicotte, F. W., Jr., Carolina Power and Light Company, Canton, N. C.
Leatherman, L. A. (Member) Bell Telephone Laboratories, Incorporated, New York, N. Y.
Lovoi, F. J., Houston Light and Power Company, Houston, Texas.
Luenberger, F. O., U. S. Electrical Motors, Inc., Los Angeles, Calif.
MacDonald, M. W., 622 West 113 Street, New York, N. Y.
Marshall, R. T., Houston Lighting and Power Company, Houston, Texas.
Martin, E. L., Tennessee Valley Authority, Chattanooga, Tenn.
McKinley, W. W., Commonwealth and Southern Corporation, Jackson, Mich.
Melcher, J. C., Leeds & Northrup Company, Philadelphia, Boston, Mass.

Miller, A. R., Union Metal Manufacturing Company, Canton, Ohio.
Minneci, S., General Electric Company, Pittsfield, Mass.
Monfort, C. E., Jr., Union Electric Company of Missouri, St. Louis.
Morton, L. W., General Electric Company, Schenectady, N. Y.
Murphy, W. J., Consolidated Edison Company of New York, Inc., New York, N. Y.
Naylor, H. E. Jr., Tennessee Valley Authority, Wilson Dam, Ala.
Nelson, C. B. (Member) Nelson Electric Supply Company, Nelson Electric Manufacturing Company, Tulsa, Okla.
Nelson, S. H., Southern New England Telephone Company, New Haven, Conn.
Pakala, W. E., Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.
Palermo, A. J., Westinghouse Electric and Manufacturing Company, Sharon, Pa.
Palmer, R. J., Virginia Public Service Company, Alexandria, Va.
Porter, W. J., Canadian Westinghouse Company, Hamilton, Ont., Canada.
Ross, A., Moloney Electric Company, St. Louis, Mo.
Ross, W. E. (Member) Canadian General Electric Company, Ltd., Toronto, Ont., Canada.
Russ, J. C., General Electric Company, Pittsfield, Mass.
Shower, E. G., Bell Telephone Laboratories, Incorporated, New York, N. Y.
Silbermann, E. F., United States Navy, New York, N. Y.
Sloan, K. H., United States Navy, New York, N. Y.
Smith, R. E. (Member) Public Service Company of Northern Illinois, Evanston.
Southall, C. S. (Member) Phoenix Engineering Corporation, New York, N. Y.
Spiller, P., Consolidated Edison Company of New York, Inc., New York, N. Y.
Stewart, G. S. (Member) Canadian General Electric Company, Toronto, Ont., Canada.
Thomas, S. H., General Electric Company, New York, N. Y.
Thring, R. G. (Member) Capital Transit Company, Washington, D. C.
Ulmer, L. S., 849 Harrison Avenue, Schenectady, N. Y.
Volle, G. H., Union Electric Company, Monsanto, Ill.
Wane, D., Canada Wire and Cable Company, Ltd., Leaside, Ont., Canada.
Weiser, L. G., Westinghouse Electric and Manufacturing Company, Louisville, Ky.
Whitner, R. L. (Member) Roller-Smith Company, Bethlehem, Pa.
Wilkoff, H. M. (Member) American Steel & Wire Company, Worcester, Mass.
Williamson, R. L., Aluminum Company of America, Atlanta, Ga.
Wright, F. T., Underwriters' Laboratories, Inc., New York, N. Y.
Zurcher, L. A., Case School of Applied Science, Cleveland, Ohio.

85 Domestic

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute record. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Boissonnault, F. L., 928 W. 8th Place, Los Angeles, Calif.
Charlton, H. C., 4827 Wilson Avenue, Montreal, Que., Canada.
Cooper, Peter G., 50 Stanton St., Schuylkill Haven, Pa.
Dadashev, Musa, 32 Zamkovaja, Ulitsa, Baku, U.S.S.R.
Fassett, Frank C., 100 Seward Ave., Detroit, Mich.
Gregory, G. A., 1217 Jefferson Street, Olympia, Wash.
Hall, John R., 1464 S. 74th St., West Allis, Wis.
Herr, Melvin D., South 228 Lincoln St., Spokane, Wash.
Kirk, W. C., 216 E. 22nd St., Owensboro, Ky.
Koziol, Roman Joseph, 174 Farmington Ave., Hartford, Conn.
Macomber, George S., Federal Power Commission, Washington, D. C.
McLean, Lee Vance, 1926 North Blvd., Baton Rouge, La.
Rizk, Kaleel S., Co. 418, C.C.C., Olustee, Fla.
Roberts, William N., 4175 Springle, Detroit, Mich.
Tribble, William Harry, 303 Park Place, Brooklyn, N. Y.

15 Addresses Wanted

# Engineering Literature

Among the new books received at the Engineering Societies Library, New York, recently are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface of the book in question.

ENGINEERING MECHANICS, DYNAMICS. By S. Timoshenko and D. H. Young. New York and London, McGraw-Hill Book Company, 1937. 323 pages, illustrated, 9 by 6 inches, cloth, $2.75. An elementary textbook on dynamics intended to give the student a thorough grounding in fundamentals. Contains discussions of 3 phases of the subject not usually contained in elementary books: vibration, elliptic harmonic motion, and relative motion.

ENGINEERING PROBLEMS MANUAL. By F. C. Dana and E. H. Willmarth. Third edition. New York and London, McGraw-Hill Book Company, 1937. 313 pages, illustrated, 8 by 5 inches, cloth, $2.25. A textbook for courses in engineering problems with the object of training the engineering student in good habits of work and study. The first 7 chapters furnish a ground work for this training; chapter 8 presents some 300 review problems; and chapter 9 contains miscellaneous tables.

MECHANICS and HEAT. (Physics for Technical Students). By W. B. Anderson. Third edition. New York and London, McGraw-Hill Book Company, 1937. 378 pages, illustrated, 9 by 6 inches, cloth, $2.50. This first volume of a set covers only mechanics and heat; sound, light, electricity, and magnetism are covered in a second volume. Intended as an elementary textbook.

TEXTBOOK of PHYSICS. By L. B. Spinney. Fifth edition. New York, Macmillan Company, 1937. 721 pages, illustrated, 9 by 6 inches, cloth $3.75. A textbook for university and college students emphasizing the practical applications of physics and illustrates the laws by reference to familiar phenomena.

THERMODYNAMICS. By H. A. Everett. New York, D. Van Nostrand Company, 1937. 430 pages, illustrated, 9 by 6 inches, cloth, $3.75. A textbook for a college course. Covers fundamentals and discusses various phases in the light of modern developments.

WIRELESS SERVICING MANUAL. By W. T. Cocking. Third revised edition. London, *Wireless World*, Iliffe & Sons, Ltd., 1937. 241 pages, illustrated, 8 by 5 inches, cloth, 5s. Covers the principles and practice of the repair and adjustment of wireless receivers. Deals in detail with methods of fault finding and describes the use of test apparatus.

THÉORIE et PRATIQUE des CIRCUITS FONDAMENTAUX de la T.S.F. By J. Quinet. Paris, Dunod, 1937. 431 pages, illustrated, 10 by 7 inches, paper, 120 frs. (140 frs., bound). An elementary study of the use of the calculus of imaginaries in the field of wireless telephony. Divided into 3 parts: the first deals with applications of the method to radio; the second shows its application to electricity; the third, application to the theory and construction of fundamental circuits in wireless telephony.

STROM- und SPANNUNGSWANDLER. By M. Walter. Munich and Berlin, R. Oldenbourg, 1937. 159 pages, illustrated, linen, 8.80 rm. Describes current and voltage transformers for switching installations. Covers current and voltage transformers as to method of operation, construction, safety precautions, connections, selection, and test procedures.

SCIENCE of SEEING. By M. Luckiesh and F. K. Moss. New York, D. Van Nostrand Company, 1937. 548 pages, illustrated, 9 by 6 inches, cloth, $6.00. A treatment of aspects not primarily considered in the various sciences with which seeing is connected. Discussions deal largely with controllable factors—physiological, typographical, illuminative.

SAGA of the SEAS. By P. B. McDonald. New York, Wilson-Erickson, 1937. 288 pages, illustrated 10 by 6 inches, cloth, $3.00. A biography of Cyrus W. Field, of which the greater part is devoted to his greatest achievement, the laying of the first Atlantic cable. Illustrated with contemporary prints and portraits.

RICHARD COCKBURN MACLAURIN. By H. G. Pearson. New York, Macmillan Company, 1937. 302 pages, illustrated, 9 by 6 inches, cloth, $3.00. A biography of the president of the Massachusetts Institute of Technology, 1909–1920. Chiefly concerned with his work in that capacity.

RADIO ENGINEERING. By F. E. Terman. Second edition. New York and London, McGraw-Hill Book Company, 1937. 813 pages illustrated, 9 by 6 inches, cloth, $5.50. Revised edition of a comprehensive engineering treatment of the more important vacuum-tube and radio phenomena.

PSYCHOLOGY of SELECTING EMPLOYEES. By D. A. Laird. Third edition. New York and London, McGraw-Hill Book Co., 1937. 316 pages, illustrated, 9 by 6 inches, cloth, $4.00. A practical treatment of the fundamental considerations in selecting men. Discusses psychological means and methods of selecting employees, and shows the employer how to find efficient employees in his own establishment, as well as in his employment office.

PREPARATION for SEEKING EMPLOYMENT. By H. L. Davis. New York, John Wiley & Sons, 1937. 39 pages, tables, 8 by 6 inches, paper, $0.25. A pamphlet for the guidance of those who seek employment for themselves or others.

PHYSICS for STUDENTS of APPLIED SCIENCE. By J. E. Shrader. New York and London, McGraw-Hill Book Company, 1937. 638 pages, illustrated, 9 by 6 inches, cloth, $4.00. Presents fundamentals necessary to give the technical student a working knowledge of physics.

MODERN THEORIES of INTEGRATION. By H. Kestelman. Oxford, England, Clarendon Press; New York, Oxford University Press, 1937. 252 pages, tables, 10 by 7 inches, cloth, $5.50. Concerned primarily with the theory of Lebesgue integration as simplified by C. Carathéodory. Designed as to be intelligible to one having a knowledge of elementary analysis. Includes discussion of Riemann integration, extensions of the Lebesgue integral, and Fourier series.

MANUAL of MATHEMATICS and MECHANICS. By G. R. Clements and L. T. Wilson. New York and London, McGraw-Hill Book Company, 1937. 266 pages, illustrated, 9 by 6 inches, leather $3.75. Contains facts and formulas useful in courses in mathematics and mechanics, also for general reference work.

LABOR'S SEARCH for MORE. By M. Keir. New York, Ronald Press Company, 1937. 527 pages, 9 by 6 inches, cloth, $3.50. Endeavors to present a record of the struggles, in recent times, of ordinary persons to improve their lot. Intended to furnish an insight as to why workers have been and are seeking more security, more income, more leisure. Strikes, trials, political campaigns, and mechanization are considered along with general economic data.

**Engineering Societies Library**
29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a co-operative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Fundamental Concepts of
# Synchronous Machine Reactances

By B. R. PRENTICE
ASSOCIATE AIEE

## Synopsis

This educational paper presents fundamental concepts of synchronous machine reactances in a form suitable for college seniors and recent graduates. Part I builds up the "physical concepts" of flux linkage and inductance, part II applies the concepts to synchronous machines, developing a physical picture of machine reactances. Part III starts with the fundamental circuit differential equations of a machine and obtains expressions for the reactances in terms of self- and mutual inductances, ending with the machine equations in the direct, quadrature, and zero axes, which give a physical picture of the machine "viewed" from these axes.

## Introduction

THIS IS an educational paper designed specifically to assist the college student in bridging the gap between his formal, fundamental education, and current engineering knowledge and practice in the field of synchronous-machine theory. The development of the modern theory of synchronous machines started about 10 years ago when Doherty and Nickle[1,2,3,4] extended Blondel's 2-reaction theory and developed methods for determining the performance of a salient-pole machine under certain steady-state and transient conditions. They proposed new definitions and divisions of synchronous-machine reactances to facilitate the analysis. Subsequently, Park[5,6] generalized the method by a more mathematical approach. Wieseman[7] and Alger[8] gave methods of calculating the reactances for design, and Park and Robertson[9] reviewed the whole field of synchronous-machine reactances from both the operating engineer's and designing engineer's viewpoints. Kilgore[10] has given additional methods for calculating the reactances and time constants in design and Wright[11] has given methods of test and test results for reactances, resistances, and time constants. Subsequent contributions in the field have been numerous and valuable.

The new ideas presented were and are considerably beyond the training given undergraduates in most colleges. This is as it should be, for there is scarcely time in a college course to do much more than give the student a sound foundation in fundamentals, and this should certainly not be sacrificed in order to progress far in special fields. A simple, easily understandable explanation of machine reactances was given by Shildneck in an article,[12] "Synchronous Machine Reactances—A Fundamental and Physical Viewpoint." This paper presents a viewpoint similar to that presented by Shildneck, and a number of others all of which have been found advantageous in the advanced course in engineering[14] of the General Electric Company in the study of synchronous-machine theory.

In the design and analysis of electrical machines, the engineer may or may not need to solve complex mathematical problems so that advanced mathematical knowledge is not essential to every engineer. However, one of his most necessary requirements is a comprehensive, clear understanding of the basic, underlying phenomena. In analysis or design this "physical picture" or "mental picture" is the foundation on which the mathematical relations are set; is the basis for approximations to simplify the formulation and solution; serves as a worthy guide in the straightforward manipulation of the mathematics; and, finally, enables the engineer to interpret his results intelligently. Such a process is present to a considerable degree in the methods of all engineers; those of a highly mathematical bent require a good physical picture to make the fullest use of their powers and those who are endowed with, or have developed, that fine sense that enables them to know the result intuitively—with little or no calculation—have the most complete mental image imaginable.

Since the possession of a clear physical picture is so essential, it is well to investigate how it may be obtained and developed. In mechanics it is easy to visualize forces, torques, velocities, accelerations, mass, etc., because one can see or feel them. The visualization of current, voltage, flux, inductance, etc., is more difficult, and special, artificial concepts such as vectors, sine waves, lines of flux, right-hand rules, etc., are needed to aid the imagination. Since but few of these artifices are either useful or valid in every possible situation, it is desirable to have at one's command a large number of points from which to view a problem. Therefore, the purpose of this paper is to aid in broadening and clarifying the reader's understanding of machine reactances by presenting the concepts from a large number of fundamental points of view.

## Part I. Fundamental Concepts of Inductance

### Circuit Concepts of Inductance

The basic study of any engineering phenomenon should ordinarily proceed by

1. Gaining or defining fundamental concepts.

A paper recommended for publication by the AIEE committee on education. Manuscript submitted November 5, 1936; released for publication May 24, 1937, by the AIEE board of directors for publication in pamphlet form and as a supplement to the 1937 TRANSACTIONS.

B. R. PRENTICE is in the engineering general department of the General Electric Company, Schenectady, N. Y.

1. For all numbered references, see list at end of paper.

2. Observing some experimental relation between the defined concepts.

3. Developing, by means of mathematics, new useful relationships based on the experimental law.

In step 3 it is frequently convenient to define and name additional auxiliary quantities to simplify the analysis and physical reasoning.

The purpose of part I is to develop clear concepts and useful properties of inductance. Proceeding, then, with step 1, primary concepts of the following quantities are presupposed:

Electromotive force or emf or voltage, $e$

Current, $i$

Time, $t$

Magnetic flux, $\phi$

Flux linkage or (simply) linkage, $\psi$

The respective units used are: volts, amperes, seconds, lines, lines-turns, the "practical" system.

The linkage of a closed circuit is defined as the sum of the numbers of flux lines linking each turn of the closed circuit. In practice the circuit need not be closed by a wire; if not, the terminals must be remote from the major magnetic field and then the voltage between the terminals is considered to close the circuit. Thus, if in the $N$ turn circuit of figure 1, $\phi_1$ lines of flux link turn 1 and $\phi_2$ link turn 2, etc., the total linkage is

$$\psi = \phi_1 + \phi_2 + \ldots\ldots + \phi_N$$

The fundamental, experimentally established law accepted as the basis (in step 2) for this analysis is Faraday's law. It states that whenever the linkage of a closed circuit changes, an electromotive force is induced equal to $10^{-8}$ times the time rate of decrease of linkage, that is,

$$e = -\frac{d\psi}{dt}10^{-8}\dagger \tag{1}$$

If the circuit is fixed in the inertial system of the observer, that is if measurements of induced electromotive force are made by, say, attaching a voltmeter to the terminals of the circuit, Faraday's law gives all of the electromotive force induced by changing flux regardless of how the change in linkage is produced, whether by self-induction, relative motion of other circuits, changing current in adjacent circuits, motion or change in permeability of the magnetic circuit, and whether the flux is visualized as moving relative to the coil and cutting it or not. This includes the case where the voltmeter is connected to a moving coil through slip rings for then, electrically, the observer is stationary with respect to the coil. An additional "motional electromotive force" is induced when the circuit is actually moving relative to the observer, as when the voltmeter is attached to a series of similar circuits through a commutator, however it is due entirely to, and is proportional to, the velocity of the circuit relative to the observer's inertial system, and not any real or supposed velocity relative to the field of flux. Page[19] writes, "Indeed the prevalent statement in elementary texts that induced electromotive forces are due to the cutting of lines of force by a conductor is not of general validity and may lead to quite erroneous conclusions in specific problems." In this paper, equations will always be originally set up with the circuits fixed relative to the observer so that Faraday's law gives the total induced electromotive force. This procedure is strongly recommended to avoid errors in circuit problems. Equations involving such a motional electromotive force will be derived in part III, resulting automatically from a transformation to co-ordinates where the observer moves relative to the circuit.

In many practical cases, the linkage of self-induction in a circuit (produced by current in the circuit) is, within reasonable accuracy, directly proportional to the current. When this is the case, the circuit is said to be linear, that is, the linkage is a linear function of the current. Thus

$$\psi = Li \times 10^8 \tag{2}$$

where $L$ is the constant of proportionality. Obviously $L$ is a physical property of the coil and its associated magnetic path. This constant of proportionality occurs so frequently in analysis that it has been named self-inductance. In practical units inductance is then defined by (2) or,

$$L = \frac{\psi}{i}10^{-8}* \text{ henrys} \tag{3}$$

Likewise, the linkage in one circuit is frequently a linear function of the current in another circuit. When this is the case the constant of proportionality is called mutual inductance which is defined by

$$\pm M_{21} = \frac{\psi_{21}}{i_1}10^{-8}** \text{ henrys} \tag{4}$$

The first subscript designates the circuit in which the effect is observed and the second that in which the cause appears. Both self- and mutual inductance can now be visualized as linkage per unit current, or in more usual terms, linkage per ampere.

If the definitions of inductance are combined with equation 1, the following relations result,

$$\left.\begin{aligned} e &= -\frac{d}{dt}(Li) \text{ volts} \\ \text{and} \\ e_2 &= \pm\frac{d}{dt}(M_{21}\,i_1) \text{ volts} \end{aligned}\right\} \tag{5}$$

† Equation 1 establishes an arbitrary convention of sign. Stated differently, a positive *applied electromotive force* gives rise to a *positive increase* in linkage, since *applied electromotive force* is opposite in sense to *induced electromotive force*. The positive direction of flux and flux linkage is related to the positive sense of electromotive force along the conductor by the right-hand rule. Thus if the fingers of the right hand are pointed in the direction of positive electromotive force along a conductor, the thumb points in the direction of positive flux and flux linkage.

* The sign here is arbitrary. Self-inductance is taken as always numerically positive so the positive sign shows that a positive current in a circuit produces positive linkage in the same circuit. The conventions established in equation 1 require that a positive applied electromotive force produce an increase in positive linkage. Hence, according to the convention chosen here, a positive electromotive force will tend to produce a positive current.

** The sign of equation 4 depends on the relative position of the 2 windings and the arbitrary directions chosen for positive current in each circuit. Thus, if positive $i_1$ produces linkage in circuit 2 in the same direction as produced by positive $i_2$, then $M$ is positive. The algebraic sign may be associated with the numerical value of $M$ rather than the literal value as used here.

Even though the inductances are independent of the value of the current, that is constant with respect to $i$, they may still vary with time, due to the motion of some part of the magnetic circuit or the relative motion of circuits. Hence, it is not permissible to write the more common relations,

$$\left.\begin{aligned} e &= -L\frac{di}{dt} \\ \text{and} \\ e_2 &= \pm M_{21}\frac{di_1}{dt} \end{aligned}\right\} \quad (6)$$

without further restricting the definition to apply to stationary coils with fixed magnetic circuits. This would obviously be folly in the study of rotating machines where circuits move relative to each other and inductances are functions of the position of the rotor, so that equations 5 will be used except when the problem involves only stationary devices.

Inductance in stationary circuits may further be visualized as electromotive-force per unit rate of change of current.

$$L = -\frac{e}{\frac{di}{dt}} \quad (7)$$

## Geometric Concept of Inductance

So far, inductance has been considered from the circuit standpoint. However, a clear physical picture of its geometric nature is most important. As defined, inductance is the constant of proportionality between linkage and current. This constant depends upon the size, shape, and permeability of the magnetic path, the number of turns in the coil and their arrangement.

Permeance $\mathcal{P}$ of a magnetic circuit is defined as the ratio of the flux to the magnetomotive force (mmf) producing it. In practical units, the magnetomotive force of a coil is $F = 0.4\pi NI$, so

$$\mathcal{P} = \frac{\phi}{0.4\pi NI} = \frac{N\phi}{0.4\pi N^2 I} = \frac{\psi}{0.4\pi N^2 I} \quad (8)$$

More precisely, if there is fractional linkage as in figure 1, the linkage is not expressible as $N\phi$ so that permeance is defined in terms of linkage as in equation 8. Then inductance, expressed in terms of the geometric property of the circuit, permeance, is

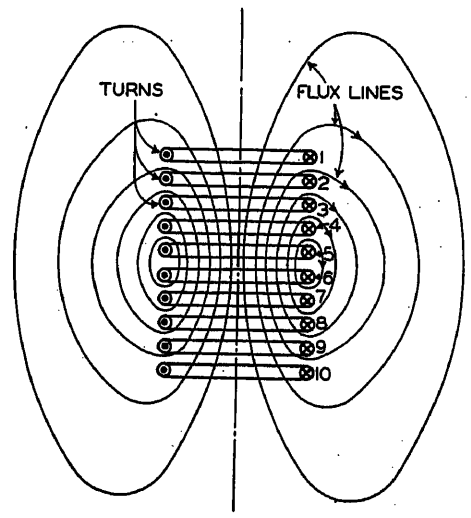
$$L = \frac{\psi}{I}10^{-8} = 0.4\pi N^2\mathcal{P}\ 10^{-8} \quad (9)$$

If the magnetic path can be characterized by single length $l$, area $A$, and permeability $\mu$, fundamental consideration of the definition shows that permeance is

$$\mathcal{P} = \frac{\mu A}{l} \quad (10)$$

and in more complex cases, is still a purely geometric constant depending on the magnetic path and arrangement of turns. Thus, inductance is proportional to the number of turns squared, the area of the magnetic path and the permeability, and is inversely proportional to the length of the magnetic path. A similar analysis of the self-inductance of, and mutual inductance between, 2 coils shows that

$$L_1 = 0.4\pi\ 10^{-8}N_1^2\mathcal{P}_1 \quad (11)$$



$$L_2 = 0.4\pi\ 10^{-8}N_2^2\mathcal{P}_2 \quad (12)$$

$$M_{12} = M_{21} = 0.4\pi\ 10^{-8}N_1N_2\mathcal{P}_{12} \quad (13)$$

where $\mathcal{P}_1$ and $\mathcal{P}_2$ represent the respective permeances of the coils and $\mathcal{P}_{12}$ that of the mutual flux path.

The foregoing concepts are extremely useful in visualizing the inductances of various windings of a machine, by examining their configuration, their relative arrangement, and the position and character of the magnetic circuit.

**Figure 1. Flux linkage**

## Concept of Leakage Inductance

Leakage, prefixed to flux, linkage, inductance, or reactance, is a very broad term being given many interpretations by various authorities. For instance, flux not crossing the useful air gap of an electromagnet is called leakage, primary flux not linking the secondary of a transformer is called leakage, and so on. In general, however, the term is applied to those portions of the quantity so described which are not useful, and on this broad viewpoint are based the various conceptions and definitions used in this paper.

In the simple transformer of figure 2,* let mutual inductance and secondary voltage, linkage, current, and self-inductance be referred to primary terms. That is, if primed quantities are referred to the primary and unprimed quantities are actual values and,

$$n = \frac{N_1}{N_2} = \frac{\text{primary turns}}{\text{secondary turns}}$$

* The transformer of figures 2, 3, and 4 is shown with primary and secondary windings placed on separate legs of the core. Obviously a power transformer would never be constructed in this manner because of the tremendous leakage reactance. However, the arrangement shown is better for the purposes of illustration than the usual concentric location of windings.

then,

$$e_2' = n\, e_2$$

$$\psi_2' = n\, \psi_2 \cong \frac{N_1}{N_2}(N_2\phi_2) = N_1\phi_2$$

$$i_2' = i_2/n$$

$$L_2' = n^2 L_2 = 0.4\pi 10^{-8}\, N_1^2 \mathcal{P}_2$$

$$M' = nM = 0.4\pi 10^{-8}\, N_1^2 \mathcal{P}_{12}$$

Since the resistances of transformer or machine windings have little effect on the distribution of flux when either alternating current of rated frequency or rapidly changing direct currents flow, and only these cases are considered here, resistances are neglected.

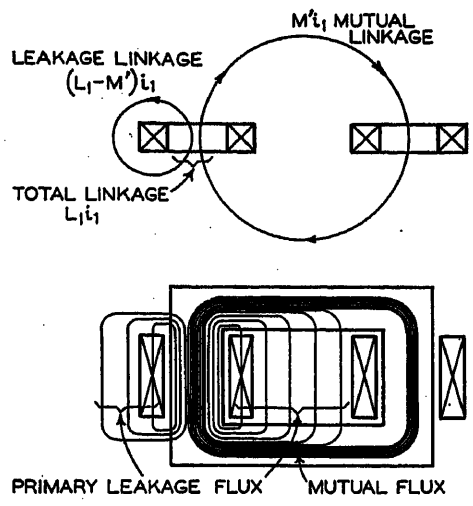


**Figure 2. Primary leakage reactance**

Flux linkage with primary excited and secondary open

Now, with the secondary open, apply sinusoidal voltage of angular frequency $\omega$ ($\omega = 2\pi f$) to the primary. In complex notation, the voltage equations are

$$\left.\begin{aligned} \mathbf{e}_1 &= j\omega\bar{\psi}_1 = j\omega L_1 \mathbf{i}_1 \dagger \\ \mathbf{e}_2' &= j\omega\bar{\psi}_2' = j\omega M' \mathbf{i}_1 \end{aligned}\right\} \quad (14)$$

and the instantaneous primary and secondary linkages are,

$$\left.\begin{aligned} \psi_1 &= L_1 i_1 \\ \psi_2' &= M' i_1 \end{aligned}\right\} \quad (15)$$

According to the concept of leakage stated previously, the nonuseful portion of the primary linkage should be defined as the leakage linkage. Obviously the nonuseful portion is that linkage which does not link the secondary or

$$\psi_1 - \psi_2' = (L_1 - M')i_1$$

The various linkages are shown graphically in figure 2.

Therefore, the open-circuit leakage inductance, $l_{oc}$, of the transformer, referred to the primary is

$$\left.\begin{aligned} l_{oc} &= L_1 - M' \\ &\text{and the leakage reactance is} \\ x_{oc} &= \omega(L_1 - M') \end{aligned}\right\} \quad (16)$$

† Bold-face type or overscoring indicates complex or vector representation of the sinusoidal quantities.

If the secondary were excited and primary open, the transformer leakage inductance referred to the primary would be $(L_2' - M')$. These leakage inductances are commonly called primary and secondary leakage inductances, respectively.

It will be evident from what follows that the transformer has an entirely different leakage inductance under every other condition of operation and the purpose of this section is to clarify these diverse concepts of the quantity and build a sound physical picture to be used in visualizing machine reactances.

Consider the transformer operating under the other extreme condition with secondary short circuited and primary excited. Then,

$$\left.\begin{aligned} e_1 &= j\omega\bar{\psi}_1 = j\omega(L_1 i_1 - M' i_2') \\ 0 &= j\omega\bar{\psi}_2' = j\omega(L_2' i_2' - M' i_1) \end{aligned}\right\} \quad (17)$$

Positive current conventions are chosen so that $M$ is negative; that is positive $i_1$ produces positive $\psi_1$, and negative $\psi_2$; positive $i_2$ produces positive $\psi_2$ and negative $\psi_1$. On elimination of $i_2'$,

$$e_1 = j\omega\bar{\psi}_1 = j\omega\left(L_1 - \frac{M'^2}{L_2'}\right) i_1 \quad (18)$$

and

$$\psi_1 = \left(L_1 - \frac{M'^2}{L_2'}\right) i_1$$

$$\psi_2' = 0$$

These linkages are shown graphically in figure 3. As

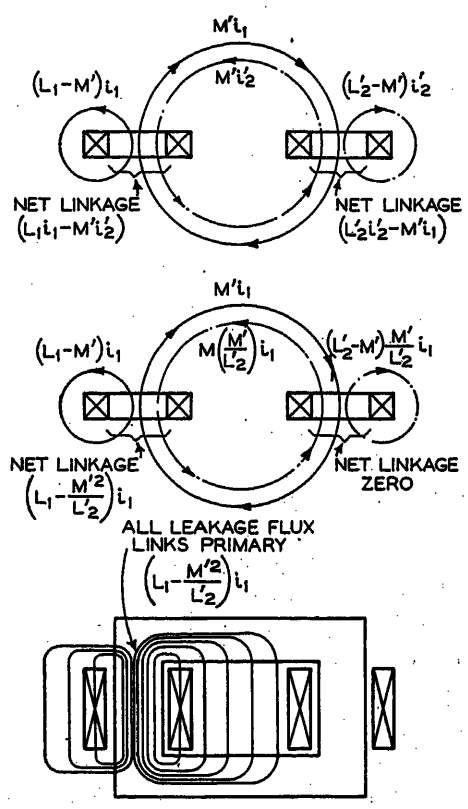

**Figure 3. Short-circuit reactance**

Flux linkage with primary excited with alternating current, secondary short circuited

Full lines show components of linkage produced by primary current, dotted lines, those due to secondary current

there is no net mutual linkage, or secondary linkage, all of the primary linkage is leakage linkage. Therefore, the transformer short-circuit leakage inductance is

$$l_{sc} = L_1 - \frac{M'^2}{L_2'}$$

and the leakage reactance is

$$x_{sc} = \omega\left(L_1 - \frac{M'^2}{L_2'}\right) \qquad (19)$$

If the secondary were excited with primary short-circuited, the corresponding leakage inductance would be

$$L_2' - \frac{M'^2}{L_1}$$ referred to the primary.

Before comparing these results with (16) it is advantageous to consider one other common definition of leakage reactance, "bucking" reactance. If magnetizing current be neglected, the primary and secondary ampere turns will be equal. This distribution of ampere turns may be accomplished physically by adjusting the voltages applied to primary and secondary such that

$$i_1 = i_2' = i$$

then,

$$e_1 = j\omega\bar{\psi}_1 = j\omega(L_1 i - M' i)$$

$$e_2 = j\omega\bar{\psi}_2' = j\omega(L_2' i - M' i)$$

Physical reasoning shows that there is no net mutual linkage. Hence the total linkage is the nonuseful linkage,

$$\psi_1 + \psi_2' = (L_1 + L_2' - 2M')i$$

The relations between the various linkages are shown in figure 4. Hence, the bucking leakage inductance is

$$\begin{aligned} l_B &= L_1 + L_2' - 2M' \\ &= (L_1 - M') + (L_2' - M') \\ &= l_{oc}\,(\text{primary}) + l_{oc}\,(\text{secondary}) \end{aligned} \qquad (20)$$

and the bucking reactance is

$$x_B = \omega(L_1 + L_2' - 2M')$$

Now to compare the 3 different values of leakage inductance note first that since

$$0.4\pi N_1^2 \mathcal{P}_1 10^{-8} = L_1 \cong L_2' = 0.4\pi N_1^2 \mathcal{P}_2 10^{-8}$$

the bucking inductance $l_B$ is approximately twice the open-circuit leakage inductance. This may be surprising for inspection of figures 2 and 4 shows that in both cases the leakage flux path in air is of the same area and length. The reason lies in the variation of the magnetomotive force across the leakage path. In figure 2, with the secondary open, the magnetomotive-force drop near the secondary leg of the core is zero and it increases nearly linearly to a maximum at the primary leg of the core. In figure 4, the bucking connection, equal magnetomotive force is supplied by both windings so that the magnetomotive force across the leakage path is essentially constant. With equal primary ampere turns in both cases, the average magnetomotive force in figure 4 is, therefore, approximately twice the average magnetomotive force in figure 2, and, therefore, so is the leakage inductance.

That the short-circuit inductance and bucking inductance are nearly equal is clear when it is noticed that under short circuit, equation 17 gives

$$i_2' = \frac{M'}{L_2'} i_1$$

and if $M' \cong L_2'$, as in a practical transformer, the primary and secondary ampere turns are nearly equal. Consequently, essentially the same magnetomotive force exists across the same path in figure 3 as in figure 4 and the corresponding leakage inductances $l_{sc}$ and $l_B$, are essentially the same. The difference is so small it cannot be calculated or tested on commercial power transformers. Subtracting equation 19 from equation 20 gives the difference

$$l_B - l_{sc} = \frac{(L_2' - M')^2}{L_2'}$$

so that the bucking inductance is theoretically slightly larger.

The consequences of this comparison are:

1. The leakage inductance of 2 "closely coupled" circuits varies as much as 2 to 1 depending on operating conditions.

2. Since magnetizing current is usually negligible compared to load or short-circuit current, either $l_{sc}$ or $l_B$ can be used and $l_{oc}$ is of only academic interest.

3. The flux distribution shown in figure 4 for bucking reactance is convenient for the design calculation of reactance but it does not occur physically either under load or short circuit. The device commonly employed for calculation is to assume a surface ($A - A'$ figure 4) dividing the primary leakage from the secondary leakage flux, approximately midway between the 2 windings. Then the reactance associated with the secondary leakage flux is calculated and called secondary leakage reactance and that associated with primary leakage flux, primary leakage reactance. This artifice, though unnecessary, yields satisfactory numerical results. The division between the 2 reactances is purely arbitrary, and they cannot be separated by test.

4. To base a physical picture on the flux distribution of figure 4, as is done in some texts, or to visualize linkage in terms of the transformer equivalent circuit tends to confuse the thinking, particularly in problems involving the law of constant flux linkage.

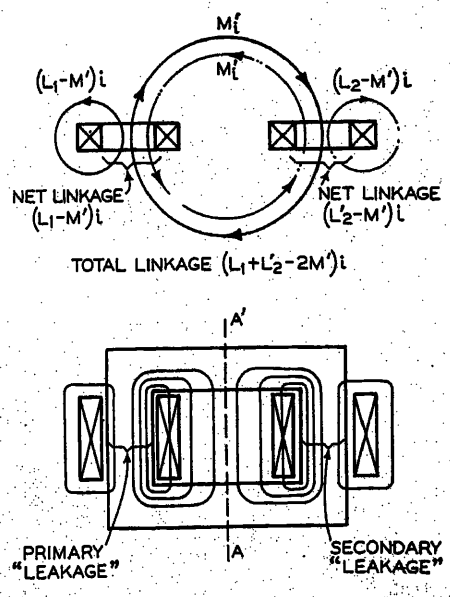

**Figure 4. Bucking reactance**

Flux linkage with primary and secondary excited with alternating current such that primary and secondary ampere turns are equal and opposite, $i_1 = i_2' = i$

Full lines show components of linkage due to primary current, dotted lines, those produced by secondary current

5. The flux distribution of figure 3 is the actual condition existing under short circuit (resistance neglected); furthermore, under load the leakage flux links only the excited winding. Therefore, this distribution should be used for purposes of visualization.

A further extension of the concepts of leakage reactance is necessary in order to visualize synchronous-machine transient reactances. Consider the static, short-circuited transformer of figure 3 to have d-c voltage applied suddenly to the primary.

$$\left.\begin{aligned} E1^* &= r_1 i_1 + \frac{d\psi_1}{dt} = r_1 i_1 + \frac{d}{dt}(L_1 i_1 - M' i_2') \\ 0 &= r_2' i_2' + \frac{d\psi_2'}{dt} = r_2' i_2' + \frac{d}{dt}(L_2' i_2' - M' i_1) \end{aligned}\right\} \quad (21)$$

Integrate both equations with respect to time.

$$\int_0^t E1\,dt = \int_0^t r_1 i_1 dt + \int_0^{\psi_1} d\psi_1$$

$$0 = \int_0^t r_2' i_2' dt + \int_0^{\psi_2'} d\psi_2'$$

In most practical machines the secondary resistance drop $r_s' i_2'$ is small compared to the induced and applied voltages; hence, if $t$ is made sufficiently small, the first term of the second equation can be made extremely small compared to the terms in the first equation and the change in secondary linkage is practically zero.

$$\psi_2' = \int_0^{\psi_2'} d\psi_2 \cong 0$$

This is one statement of the law of constant flux linkage. Therefore,

$$\psi_2' = L_2' i_2' - M' i_1 \cong 0$$

and

$$i_2' \cong \frac{M'}{L_2'} i_1,$$

and equation 21 becomes

$$E1 \cong r_1 i_1 + \left(L_1 - \frac{M'^2}{L_2'}\right)\frac{di_1}{dt}$$

Hence, exactly initially ($t$ infinitesimally small), and approximately for the first short interval of time, the effective inductance of the short-circuited transformer with suddenly applied d-c voltage is identical with its a-c short-circuit inductance. As time increases indefinitely the effective inductance gradually approaches the self-inductance $L_1$.

On first notice it might appear that neglecting the secondary resistance drop in deriving this expression is not warranted when it is intended to use this case as an analogy to machine circuits with the field winding as secondary; for the field resistance is large and cannot be neglected, particularly in determining rates of decay of currents. However, it must be emphasized that the expression is exact when the time interval is infinitesimally small and the effect of high resistance is to shorten the time during which the approximation is a good one.

Physically, this may be explained by realizing that when a sudden voltage is impressed on the primary and the primary current builds up on an exponential type curve, simultaneously the secondary current builds up on an exponential type curve, tending to keep the secondary linkage zero. During the first few instants of time the secondary linkage is essentially zero, and the primary flux is forced entirely into the leakage paths of very low permeance as shown in figure 3.

The constant flux linkage theorem was presented by R. E. Doherty[17] as a tool in the analysis of short-circuit problems. The principles involved are very useful in visualizing and analyzing transient phenomena and it is believed that better use of them could be made in the colleges. Although it will be used, a thorough treatment of the theorem is outside the scope of this paper. It may be briefly stated as follows: the *total linkage* in any closed electrical circuit cannot change instantly. A "closed circuit" is one which involves no infinite voltages or resistances but it may contain any number of finite resistances, inductances (including mutual inductance), and the inductance may vary as a function of time. The rate at which the total linkage does vary is, by Faraday's and Ohm's laws, proportional to the difference between the applied electromotive force and the $IR$ drop.

For the purposes of this paper, the discussion of leakage inductance and reactance serves to build up the following physical picture. When a closed winding is in magnetic proximity to another winding, and the latter winding is excited with either a-c or suddenly applied d-c voltage, the flux linkage of the closed winding remains essentially constant and practically all of the newly created flux present links the excited winding as shown in figure 3. This newly created flux passes through the very low permeance leakage path between the 2 windings so that the effective inductance and reactance are correspondingly small. The initial effective inductance of the excited winding is $(L_1 - M'^2/L_2')$ or approximately $(L_1 + L_2' - 2M')$.

## Part II. Synchronous-Machine Reactances—Physical Viewpoint

A fundamental physical picture of each of the more important synchronous-machine reactances will be built up on the basis of the concepts established in part I and considering the effects of a salient-pole rotor and its associated, closed field windings. Laminated cylindrical-rotor machines, being generally easier to visualize, are mentioned only as a special case of the salient-pole machines. Solid cylindrical-rotor machines may be approximately analyzed by salient-pole methods but a more comprehensive theory such as presented by Concordia and Poritsky[18] is necessary for an accurate treatment of transient problems. These concepts are based on the actual phenomena occurring within the machine. It is also possible to view the phenomena from the terminals of the machine, that is, on the basis of actual tests which might

* The unit function, 1, indicates that the voltage is zero until time zero, $E$ thereafter.

be conducted. Hence, in order to broaden the understanding of these reactances still further, a few methods of determining them by tests—which are simple enough to enhance the viewpoint without resorting to a detailed mathematical analysis—will be included in the discussion of each reactance. Finally, the analytic approach, which gives an understanding of the reactances from still a different angle, will be presented very briefly in part III.

A symmetrical, 3-phase, armature winding is assumed, and saturation, hysteresis, and eddy current losses are neglected. The effect of circuit resistance is neglected in visualizing the linkages but obviously resistance cannot be neglected in visualizing the decay of currents. The field structure and field windings are assumed to be symmetrical about the center lines of the poles, (direct axis) and also symmetrical about the axes midway between the poles (quadrature axis).

## Armature Leakage Reactance $x_l$

The armature leakage reactance of a synchronous machine is a part of nearly all of the other armature reactances, so that a knowledge of it is prerequisite.

If a voltage be applied to the armature terminals such that balanced, sinusoidal, fundamental-frequency, 3-phase currents of normal phase rotation (positive-sequence†) flow in the armature winding, these currents will set up a rotating flux wave in the air gap. Due to the finite number of slots, phases, etc., this flux wave will be composed of fundamental and harmonic components. For instance, the 3-phase currents produce a rotating magnetomotive force which has a fundamental component rotating forward at synchronous speed, a backward rotating fifth harmonic, a forward rotating seventh harmonic, etc., the relative magnitudes of which depend on the winding arrangement. These harmonic magnetomotive forces traveling at speeds different from that of a salient-pole rotor will produce, by interaction with the varying permeance of the air gap, flux harmonics of various orders, traveling at different speeds. (If the rotor is cylindrical and laminated the harmonic magnetomotive forces will give rise to harmonic fluxes of corresponding order and speed of rotation. However, if the cylindrical rotor is solid, currents will be induced in it changing the magnitude of the flux harmonics.) Some of these flux harmonics will be of such order and speed that they will induce voltage of fundamental frequency in the armature. However, they induce purely reactive armature voltage so that their effects are included in the armature leakage reactance, and the corresponding linkage is called differential leakage flux linkage.*

In addition to this armature linkage due to air gap flux harmonics, there will be armature linkages due to slot flux and flux in the end winding. If the differential, slot, and end winding linkages are added, the sum is defined to be the total armature leakage flux linkage. The ratio of this linkage in one phase to the armature phase current producing it $\times 10^{-8}$ gives the armature leakage inductance in henries. This value is multiplied by $\omega$, $\omega = 2\pi f$ (where $f$ is rated frequency in cycles per second) is the armature leakage reactance, per phase, in ohms. The ratio of this value to "base ohms" is $x_l$ in per unit.**

It should be noted that the armature leakage reactance includes the effect of that part of the mutual linkage between phases, due to other than the fundamental flux wave and, therefore, is a "3-phase" reactance, applicable without modification only under 3-phase balanced operation or when unbalanced operation is analyzed in terms of its symmetrical components. Unfortunately, this reactance cannot be determined directly from test. However, it is part of nearly all subsequent reactances, and a physical picture of it is, therefore, desirable.

## Direct Synchronous Reactance $x_d$

If positive-sequence currents flow in the armature, as discussed under $x_l$, the major component of armature linkage is due to the synchronously rotating, fundamental component of the air-gap flux which exists in addition to the leakage flux linkage. Unlike the latter, the amount of linkage due to the fundamental is greatly affected by the position of the field structure. If the unexcited field is rotated synchronously so that the poles are always directly in line with the fundamental component of armature magnetomotive force, maximum permeance is presented to the magnetomotive force as shown in figure 5 and maximum total armature linkage per armature ampere results. Under these conditions the ratio of the linkage in one phase to the current in that phase‡ $\times \omega 10^{-8}$ gives the direct synchronous reactance, per phase,§ in ohms. The ratio of this value to base ohms is $x_d$ in per unit. This reactance obviously includes the armature leakage reactance.

The physical picture of this reactance can be broadened by viewing the phenomena from the terminals of one phase. The phase linkage, due to leakage flux and the synchronously rotating, fundamental, air-gap flux, pulsates sinu-

† The usual symmetrical component[16] terms will be used: Positive-sequence (or positive phase-sequence) refers to those symmetrical components of quantities (such as current or voltage) which are of normal (positive) phase rotation; negative-sequence refers to those symmetrical components which are of opposite to normal (negative) phase rotation; zero-sequence refers to those symmetrical components which are of the same time phase or are "in phase" with each other. Any unbalanced 3-phase voltages or currents may be resolved into the 3 sets of symmetrical components listed above. However, an understanding of the system of analysis called symmetrical components is not essential for this paper, it being simply necessary to know the meaning of the defined terms.

* Voltage harmonics of other than fundamental frequency must in all cases be produced by permeance variations or other external influences, and are not themselves causes of reactance.

** The per-unit representation of quantities is similar to the familiar per-cent representation except that the per-unit value of a quantity is the ratio of the actual quantity to an arbitrary amount called the base; whereas the per-cent value is this times 100. Thus, if each phase of a 3-phase machine is rated at 500 amperes and 2,200 volts, "base ohms" is based on the machine rating and is

$$\frac{\text{rated volts}}{\text{rated current}} = \frac{2{,}200}{500} = 4.4 \text{ ohms}$$

Then if a particular reactance (or resistance or impedance) had an actual value of 8.8 ohms, its per-unit value would be

$$\frac{\text{actual ohms}}{\text{base ohms}} = \frac{8.8}{4.4} = 2 \text{ per unit}$$

If machine reactances are expressed in per unit on the machine rating as base, their numerical values have definite significance to one familiar with machines, and do not vary greatly with the size of machines as do ohmic values. This advantage of the per-unit system will become more apparent when table I is studied.

‡ It has not been stated whether the linkage and current used should be instantaneous, root-mean-square, peak, or some other value. It makes no difference as long as the same kinds are used for both. For indeed, the linkage is a linear function of the current, and their ratio is independent of the kind.

§ Invariably synchronous machine reactances are stated on a per phase base so that further mention of this fact will be omitted.

soidally at normal frequency producing the sinusoidal phase voltage, resistance drop being neglected. Now the axis of the rotating fundamental of armature magnetomotive force will coincide with a phase axis at the instant that that phase current is a maximum. Also, since the field pole is moving synchronously in line with the magnetomotive-force wave, it will be precisely in line with the phase at that instant. Consequently, the phase linkage at that instant will be the maximum possible which can be produced by armature current under any condition. This is the peak value of the sinusoidally varying linkage which induces the sinusoidal phase voltage. As they are proportional, the ratio of the phase voltage to the phase current gives $x_d$ in ohms. It is also apparent that $x_d$ is the largest possible 3-phase armature reactance definable.

In practice it is difficult to rotate the field structure mechanically so that the direct axis is always exactly in line with the axis of the rotating armature magnetomotive force. Consequently such a method is unsuited for the experimental determination of the reactance by test. However, when a synchronous machine is short circuited it is a well-known fact that the current which flows is almost entirely reactive, and, therefore, the armature magnetomotive force is almost directly in line with the poles, tending to demagnetize them. Since this condition obtains automatically it is suitable for determining $x_d$.

Saturation is neglected so the flux linkage in any one circuit at any particular instant of time is a *linear* function of the magnitudes of the currents existing in every other winding in the machine at that instant and the principle of superposition may then be used to determine the linkage. Thus, the linkage in one circuit due to the currents in certain circuits flowing alone may be determined; that linkage due to the rest of the currents may be determined separately; and then the 2 values of linkage thus obtained when added give the total linkage in the one circuit with all currents flowing. This is true provided that the motion of the rotor is the same in both cases.

Consider the conditions which must exist under steady-state, symmetrical, short circuit. The terminal voltage is zero. Neglecting resistance drop, the net armature linkage including leakage flux linkage, must, therefore, also be zero. Since the net armature linkage is produced by the armature currents and field current acting at the same time, the armature magnetomotive force opposes the field magnetomotive force; the armature linkage due to all armature currents acting alone must be exactly equal to, and opposite in direction to, the armature linkage due to the field current acting alone. If the field current were acting alone (open circuit) a certain terminal voltage would exist which would be proportional to the armature linkage produced by the field current. Now suppose that the armature currents flow alone (field open circuited). Since the armature linkage has the same value, but is in the opposite direction, the voltage which must have been applied to produce the armature currents must be exactly the same as the terminal voltage induced under open circuit. But notice, when the armature currents flow alone the case is exactly that used to define $x_d$. That is, they are positive phase-sequence, the magnetomotive force produced by them is in line with the poles, and the field is open. Hence, by definition, the ratio of the terminal phase voltage, which would produce the armature currents alone, to the armature phase current gives $x_d$ in ohms, but this voltage is the same as the open circuit voltage before short circuit. Finally, then, $x_d$ is the ratio of the open-circuit terminal voltage resulting from a certain field current to the steady-state, short-circuit, armature current resulting from the same field current.

$$x_d = \frac{E_{\text{open circuit}}}{I_{\text{short circuit}}} \text{ ohms}$$

Obviously these quantities can be determined from the saturation curve and synchronous impedance curve of the machine.*

This discussion of a possible test to determine $x_d$ has served 2 purposes. First to broaden the physical picture and second to indicate how the principle of superposition may be applied in the solution of synchronous machine problems. For standard definitions and methods of measuring this and subsequent reactances, see the AIEE Standards.[21]

## Quadrature Synchronous Reactance $x_q$

With positive-sequence, steady-state currents flowing in the armature and the unexcited field structure rotated mechanically at synchronous speed, such that the interpolar spaces (quadrature axis) are directly in line with the peaks of the rotating armature magnetomotive-force wave, minimum permeance is presented, and the armature linkage will be the minimum for any position of the poles. The flux paths may be visualized by inspecting figure 6 which shows graphically that the permeance of the air gap in the quadrature axis is much lower than that in the direct axis. (If the rotor is cylindrical the permeances will be equal and $x_d = x_q$.) Under this condition the armature linkage per ampere $\times$ $\omega 10^{-8}$ gives the quadrature synchronous reactance, $x_q$, in ohms. The ratio of this value to base ohms gives $x_q$ in per unit. This reactance includes the leakage reactance $x_l$.

If viewed from the armature terminals, the magnitude of the root-mean-square, reactive voltage induced in a phase will be a minimum when the interpolar space is in line with the magnetic axis of the phase at the instant when the current in the phase is a maximum, for if the field structure had any other position at the instant that the phase current was a maximum, a greater armature linkage would result. The ratio of the phase voltage to the phase current under this condition gives $x_q$ in ohms. It is important to note that both $x_d$ and $x_q$ are defined with the field structure in a symmetrical position with respect to the rotating magnetomotive-force wave. Thus, in either case, the field structure has no tendency to be turned by the flux in either direction so that there is no magnetic torque. Therefore, since no electrical power is transferred to the

* The saturation curve is a plot of terminal voltage versus field current and the synchronous impedance curve is a plot of steady-state, short-circuit current versus field current. Normally, the ratio is taken at rated terminal voltage, and to obtain an unsaturated value for $x_d$ the field current at rated terminal voltage on the "air-gap line" is used. The "air-gap line" is a straight line tangent to the straight portion of the magnetization curve.

rotor, the currents are purely reactive (neglecting resistance) and it is legitimate to define a reactance for each case as the ratio of total voltage to total current.

It is difficult to rotate the field structure mechanically so that the quadrature axis is always exactly in line with the armature magnetomotive force for if it deviates slightly a torque will appear (reluctance torque) tending to pull the direct axis into line with the armature magnetomotive force. Hence it is even more impractical in this case to rotate the field structure in its proper position than it was in the case of direct synchronous reactance. However, suppose that the unexcited field is rotated mechanically in the direction of the synchronously revolving armature magnetomotive force, but at a speed slightly below synchronism, and at the same time positive phase-sequence voltages are impressed at the terminals. Obviously the current will be modulated at slip frequency, being a maximum when the quadrature axis is in line with the armature magnetomotive force and a minimum when the direct axis is in that position. Also, due to the reactance in the supply line, the applied voltage will probably be modulated at slip frequency being a maximum at minimum current. Figure 11 is an oscillogram showing this variation. If the applied voltage and current in one phase are observed by means of instruments and the slip is small enough, the maximum and minimum values of the modulated current and voltage can be read directly from instruments. Minimum voltage and maximum current will occur when the quadrature axis is in line with the magnetomotive-force wave peak. Quadrature synchronous reactance in ohms

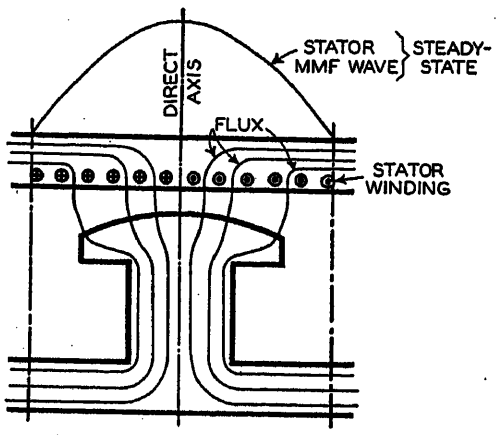

**Figure 5. Direct synchronous reactance flux paths**

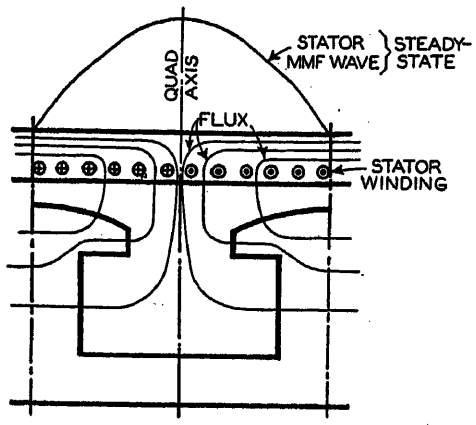

**Figure 6. Quadrature synchronous reactance flux paths**

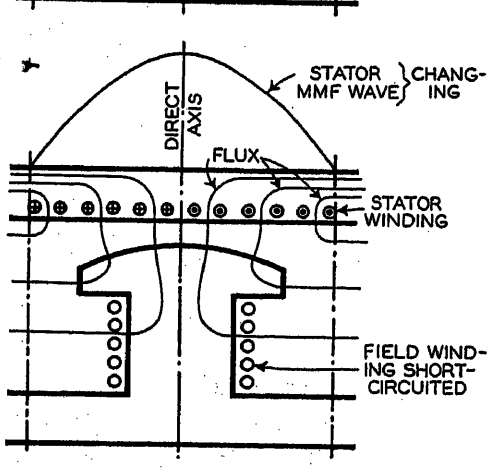

**Figure 7. Direct transient reactance flux paths**

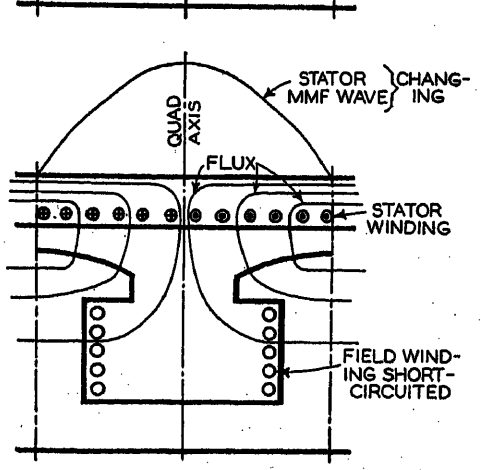

**Figure 8. Quadrature transient reactance flux paths**

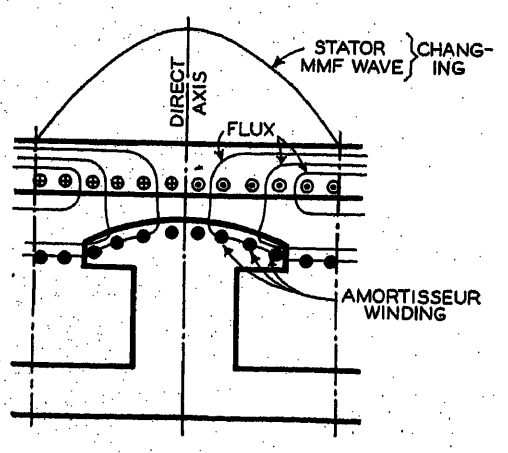

**Figure 9. Direct subtransient reactance flux paths**

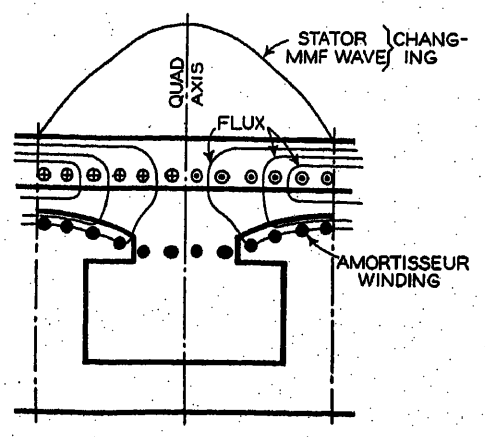

**Figure 10. Quadrature subtransient reactance flux paths**

is then the ratio of minimum voltage to maximum current. From this same test, the ratio of maximum voltage to minimum current gives direct synchronous reactance in ohms.

## Direct Transient Reactance $x_d'$

Direct synchronous reactance is analogous to the self-inductance of the primary of the open-circuit transformer of figure 2. This is true regardless of whether the rotor rotor circuits, such as the amortisseur or damper windings, imagined to be open. Suddenly, terminal voltages are applied at such an instant that fundamental-frequency, positive-sequence armature currents result* and produce a rotating magnetomotive force the axis of which is directly in line with the poles. This condition is identical with that used for defining direct synchronous reactance except that the voltages are now suddenly applied. The sudden appearance of the magnetomotive force in the direct axis is resisted by the current induced in the closed field winding

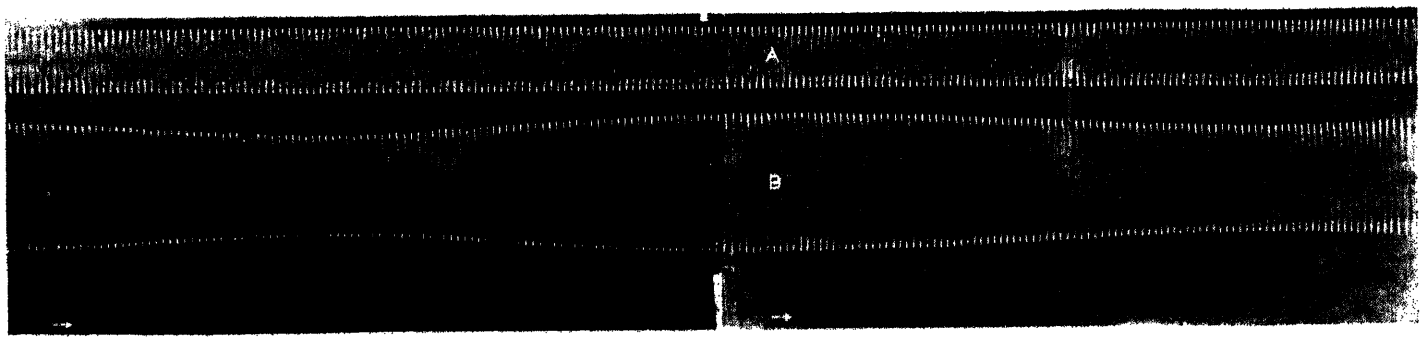

**Figure 11. Determination of $x_d$ and $x_q$ by a "slip test"**

Balanced voltages applied to armature, field open and rotated near synchronous speed

A—Armature voltage
B—Armature current

$$x_d = \frac{\text{maximum voltage}}{\text{minimum current}} \qquad x_q = \frac{\text{minimum voltage}}{\text{maximum current}}$$

circuits are open or closed because, as defined, the steady-state, constant-magnitude, rotating fundamental of the armature magnetomotive force is always stationary with respect to the poles. Since there is no rate of change of magnetomotive force when viewed from the field structure, there will be no currents induced in any field winding, so that the armature magnetomotive force meets a constant permeance, the value of which is determined only by the air gap and magnetic circuit and not by the magnetomotive force of any field winding. Theoretically, any problem involving transformer circuits can be solved in terms of the self- and mutual inductances of windings. Likewise, any synchronous machine problem can theoretically be solved in terms of the synchronous reactances and the self- and mutual inductances of rotor circuits with themselves and with the armature. However, transformer-circuit calculations are greatly simplified and their accuracy improved by employing the short-circuit reactances between windings instead of self- and mutual inductances. A similar simplification can be made in synchronous machine calculations by the use of reactances which *take into account the transient effects of closed rotor windings.*

Thus, when conditions are changing (transient conditions) induced currents will flow in the closed rotor circuits, modifying the effective permeance of the armature flux paths and reducing the corresponding effective reactances. These reactances are analogous to the transformer short-circuit reactance discussed in part I which takes the effect of the closed secondary into account.

Consider the machine operating at normal speed with the unexcited main field winding closed, but with all other just as the current in the transformer secondary of figure 3 resisted a sudden change in the primary magnetomotive force when a d-c voltage was suddenly impressed. Of course, the induced field current will die out eventually. However, during the first interval of time the field current will maintain the field linkage at practically zero value, and the armature flux is forced into the low permeance paths of the interpolar space, see figure 7, just as the transformer primary flux is forced into the leakage path between the primary and secondary in figure 3. The armature linkage per symmetrical, fundamental-frequency, armature ampere will be much less than under synchronous conditions and its value $\times \omega 10^{-8}$ gives direct transient reactance, $x_d'$, in ohms. This value divided by base ohms gives $x_d'$ in per unit.

In order to visualize direct transient reactance from a test which might actually be conducted, it will again be necessary to conduct one which is different from the conditions used to define the reactance. Since we are now dealing with transient quantities, it will also be necessary to employ an oscillograph rather than instruments. Just as in the case of direct synchronous reactance, superposition allows a determination of direct transient reactance from a 3-phase short-circuit test; for in transient as well as steady short circuit the rotating fundamental component of armature magnetomotive force is directly in line with the poles tending to demagnetize them. Now it is possible to superpose the results of various *components* of the current in one circuit, considered separately, just as it is

* It is shown later that suddenly applied currents tend to contain d-c and harmonic components. Hence to obtain the current used in defining $x_d'$ an unusual voltage would be required.

possible to superpose the results of *total currents* in separate circuits. For indeed, the linkage in any one circuit is directly proportional to the total current in each circuit, and hence, to the sum of any components into which each current may be divided in every circuit in the machine. Before short circuit, a certain steady field current existed which gave rise to a certain a-c terminal voltage. After, short circuit armature currents will suddenly start to flow. The sudden magnetomotive force appearing before the field will be resisted by a sudden increase in field current over its initial value. Also after short circuit the terminal voltage is zero, so the change of armature linkage must also be zero. Consequently, the armature linkage produced by the armature current plus that produced by the *increase* in field current has exactly the same value and is in opposite direction to the armature linkage produced by the initial value of field current acting by itself. Now this armature linkage, produced by the armature current plus the *increase* in field current acting together, is produced under exactly the same conditions which were used to define direct transient reactance; for indeed, the armature magnetomotive force appears suddenly in the direct axis and induces field current which opposes it, and the ratio of the symmetrical part† of the phase voltage to the symmetrical part of the phase current is $x_d'$. However, this voltage has exactly the same magnitude as the open-circuit voltage which existed before short circuit. Therefore, the ratio of the voltage before short circuit to the symmetrical part of the armature current immediately after short circuit is direct transient reactance, $x_d'$, in ohms.

In the foregoing analysis one important part of the phenomena has been barely mentioned, the presence of d-c and harmonic components in the armature current. At the instant of short circuit each of the 3 armature phase circuits will be linked by some fraction of the flux produced by the main field excitation. Thus if the short circuit occurred at the instant the direct axis was in line with phase *a*, phase *a* would have maximum positive linkage and the linkages in phases *b* and *c* would be negative and half the maximum.

By the law of constant flux linkage, currents will flow in the armature and field to maintain the armature and field linkages at essentially constant value for a short time after short circuit. The jump in d-c field current to maintain the field linkage constant in the face of the magnetomotive force produced by the a-c, short-circuit armature current has been emphasized. However, the a-c armature current and d-c field current could produce constant armature phase linkages of only zero value. Hence, the armature current will contain d-c components to maintain the initial linkage. This results in a displaced wave of phase current such as shown in figure 13. An oscillogram of symmetrical short-circuit phase current when the phase linkage happened to be zero at the instant of short is shown in figure 12. Here no d-c component was necessary to maintain zero linkage.

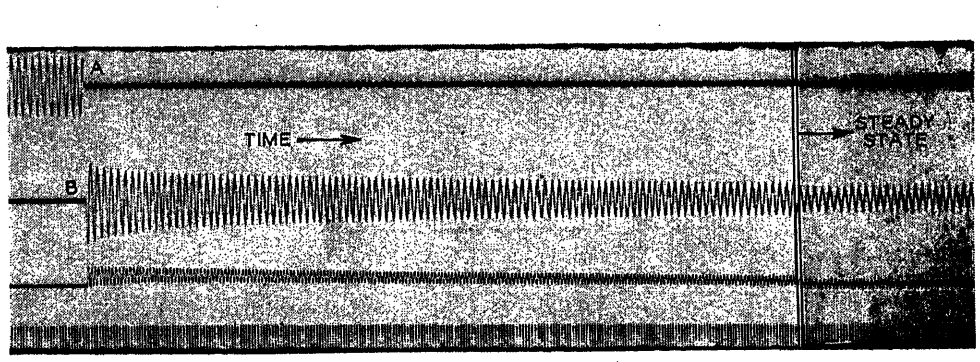

**Figure 12. Nearly symmetrical short-circuit armature current on a 35,000-kva 25-cycle water-wheel generator**

*A*— Armature voltage
*B*— Armature current

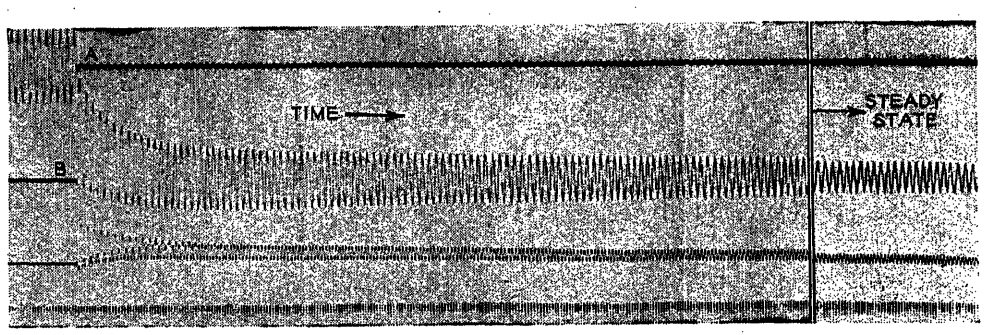

**Figure 13. Nearly pure asymmetrical short-circuit armature current on the same machine as figure 12**

*A*— Armature voltage
*B*—Armature current

The d-c component of armature current results in a stationary magnetomotive force in the air gap. This would produce fundamental-frequency linkage in the field did not a fundamental-frequency field current flow to prevent it. The fundamental-frequency field current gives a pulsating magnetomotive force stationary with respect to the poles which may be resolved into 2 fundamental, magnetomotive-force waves rotating, one forward and one backward with respect to the poles at synchronous

† The symmetrical part of a wave is the part symmetrical about the axis of zero deflection, that is the residue after the d-c component has been subtracted.

speed. The backward rotating component is stationary with respect to the armature and opposes the d-c armature magnetomotive force. The forward rotating component is traveling at twice normal speed with respect to the armature so that a second-harmonic component of armature current must flow to prevent a change of armature linkage. This current will also have its effect on the field and so on. The purpose of this discussion is to complete, in a measure, the physical picture of the phenomena on short circuit. It is evident that the different components of current, existing for different purposes, meet different permeances. Consequently, direct axis transient reactance is defined for only the symmetrical, fundamental-frequency part of the armature current.

The actual test to determine the initial value of short-circuit current could be conducted by taking enough oscillograms of the current, till one was obtained which was symmetrical, or by graphically determining the symmetrical part of an asymmetrical wave, then drawing a line through the peaks of the successive decaying armature current waves and project it back to the time of short circuit neglecting the first few peaks of current which will be discussed under subtransient reactance. The initial value of short-circuit armature current may then be estimated as in the dotted line of figure 14 which was obtained from the oscillogram figure 12. Of course, if the peak value of the current is used, the peak value of the voltage must also be used.

## Direct Subtransient Reactance $x_d''$

In defining direct transient reactance all field windings except the main field winding in the direct axis were assumed to be open. An amortisseur winding as shown in figure 9 may be present in both the direct and quadrature axes. If it is, and armature voltages are suddenly applied to the machine so that armature currents increase rapidly, current will be induced in the amortisseur winding resisting the change in flux in addition to the current induced in the main field winding. Since the amortisseur winding is closer to the air gap than the main field, the permeance of the air-gap leakage-flux paths under this condition is still less than the corresponding permeance in the case of direct transient reactance. The corresponding armature linkage and reactance are also less. Invariably, the per-unit resistance of the amortisseur winding is considerably larger than the per-unit resistance of the main field, so that the induced amortisseur currents tend to die out much more rapidly. The high resistance is used to get the high induction-motor torque required for starting or to produce effective damping if the purpose of the amortisseur is to damp out oscillations. This rapid decay gives rise to the term subtransient reactance, indicating a very high speed phenomenon while transient reactance is the lower speed phenomenon caused by the main field windings.

Let the field structure be rotated mechanically at synchronous speed with the main field winding unexcited but closed, and all other field windings closed. If terminal voltages are now impressed at such an instant that positive-phase-sequence currents are produced, an armature magnetomotive force will be set up which rotates synchronously with its axis directly in line with that of the poles and amortisseur winding currents will be induced resisting the establishment of armature flux. The armature flux is then forced into the very low permeance air-gap leakage path as shown in figure 9 and the net armature linkage per armature ampere under this condition $\times \omega 10^{-8}$ gives direct subtransient reactance in ohms. This value divided by base ohms is $x_d''$ in per unit.

The test procedure described for determining direct transient reactance may also be used to determine direct subtransient reactance. If a closed amortisseur winding is present, the short-circuit current will have a form such as shown in figure 12 or 13. The same argument used in

**Table I. Components of Synchronous Machine Reactances**

* $x_0$ varies from about 15 per cent to 60 per cent of $x_d''$, depending upon winding pitch.
** These values apply to machines with amortisseur windings. For water-wheel generators without amortisseur windings, $x_d'' = x_d'$, $x_q'' = x_q' = x_q$. $x_2$ will be an average of $x_d''$ and $x_q''$ and $x_0$ will be unchanged.

deriving the expression for $x_d'$ from the short-circuit test leads to the obvious result that $x_d''$ is the ratio of the open-circuit voltage existing before short circuit to the symmetrical part of the armature current existing immediately after short circuit. This value of the current may then be obtained by projecting the line connecting the peaks of the short-circuit current back to the zero axis as shown in figure 14. It has been pointed out that the amortisseur-winding currents die out very rapidly, so that their effect soon becomes negligible. Hence, $x_d'$ may be determined from the same test by projecting the line connecting the more slowly decaying peaks of current back to the zero axis as shown.

## Quadrature Transient Reactance $x_q'$

Consider the machine to be operated as in the case of direct transient reactance except that the terminal voltages are applied at a different instant so that the axis of the suddenly appearing armature magnetomotive force is now directly in line with the quadrature axis. Now if there are no closed rotor circuits in addition to the main field winding, the armature flux will pass through the main field winding from one side to the other as shown in figure 8. The net field linkage due to this flux is zero and hence no main-field-winding currents will be induced tending to distort the flux. The armature linkage under this condition per armature ampere $\times \omega 10^{-8}$ gives quadrature transient reactance in ohms. This value divided by base ohms gives $x_q'$ in per unit.

Since the permeance presented to the armature magnetomotive force under this condition is exactly the same as that presented under the conditions defining quadrature synchronous reactance, the armature linkage per ampere will be the same in both cases, and the quadrature transient reactance is exactly equal to the quadrature synchronous reactance. This is literally true if the field structure is perfectly laminated. If the machine has a solid rotor, currents will be induced in the rotor iron resisting the change in flux so that $x_q'$ will be less than $x_q$.

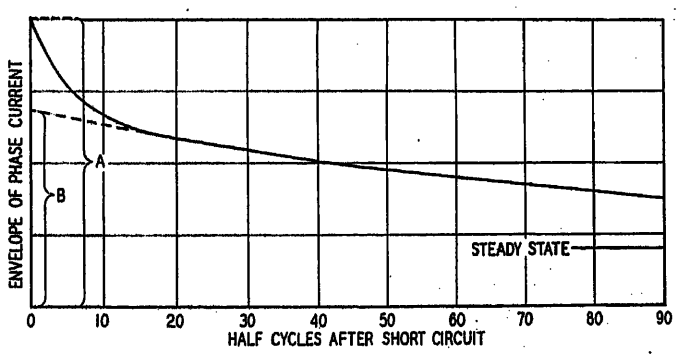

**Figure 14. Determination of $x_d'$ and $x_d''$ from test oscillogram, figure 12**

Curve shows envelope of symmetrical short-circuit phase-current wave. $x_d''$ inversely proportional to initial current $A$.
Dotted curve shows envelope of symmetrical current after high-speed transient has been subtracted. $x_d'$ inversely proportional to $B$

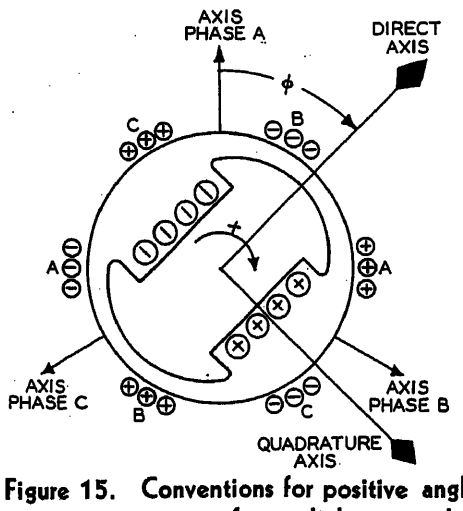
## Quadrature Subtransient Reactance $x_q''$

If an amortisseur winding exists in the quadrature axis, and terminal voltages are suddenly applied such that fundamental-frequency positive-sequence currents flow so that the resultant rotating armature magnetomotive force is in line with the quadrature axis of the mechanically rotated field structure, current will be induced in the amortisseur winding tending to maintain its linkage zero and forcing the armature flux into the very low permeance air-gap path as shown in figure 10. Under this condition the armature linkage per armature ampere $\times \omega 10^{-8}$ gives quadrature subtransient reactance in ohms. This value divided by base ohms gives $x_q''$ in per unit.

No simple convenient method of test exists to aid in visualizing this reactance. Methods of test exist[10,11] but the mathematical analysis, required for establishing them, complicates the physical picture.

## Negative-Sequence Reactance $x_2$

If terminal voltages are impressed such that fundamental-frequency negative-sequence currents flow while the unexcited field structure with all field windings closed is rotated mechanically at synchronous speed in the forward direction, the armature magnetomotive force will be traveling in the opposite direction at synchronous speed and hence will be traveling with twice synchronous speed with respect to the field structure. Then alternating currents of twice normal frequency will be induced in the rotor circuits, holding the field linkage at essentially zero value. This case is analogous to the a-c excited, short-circuited transformer of figure 3 for in the transformer an a-c magnetomotive force attempts to force flux through the short-circuited secondary and alternating currents are induced in the secondary holding the secondary linkage zero. In the case at hand the armature flux is forced into the very low permeance air-gap paths. Of course the actual permeance of the air-gap path varies as a function of time, for the armature magnetomotive force meets alternately the direct and quadrature axis. Under this condition the average armature linkage per armature ampere $\times \omega 10^{-8}$ gives the negative-sequence reactance in ohms. This value divided by base ohms is $x_2$ in per unit.



The permeance presented to the armature magnetomotive force at the instant that the magnetomotive force is over the axis of the poles is evidently essentially the same as the permeance presented under direct subtransient conditions and the effective reactance if the permeance were constant at this value would be $x_d''$. However, an instant later the magnetomotive force is directly over the quadrature axis and at this instant the effective reactance is $x_q''$. Hence, the average value of $x_2$ must lie between $x_d''$ and $x_q''$. For most purposes the value of $x_2$ is taken as the arithmetic average of $x_d''$ and $x_q''$.

$$x_2 = \frac{x_d'' + x_q''}{2}$$

The conditions used to define negative-sequence reactance may also be used to measure it. It is simply necessary to rotate the rotor mechanically at normal speed with the main field winding unexcited but short circuited, and to apply terminal voltages such that fundamental-frequency negative-sequence currents flow in the armature. The ratio of the average phase voltage to the average phase current under this condition gives $x_2$ in ohms. Tests may also be made with the rotor stationary[21] but here again, they are of little use for visualization.

## Zero-Sequence Reactance $x_0$

Zero-sequence currents are defined as currents which would flow if the 3 line terminals of a Y-connected machine were joined and single-phase voltage applied between the neutral and the terminals. Under this condition currents will flow in the 3 armature windings and will be of the same time phase. If such currents be impressed on a synchronous machine, no space fundamental of air-gap magnetomotive force will be produced so that the motion of the rotor is unimportant and the reactance is very small. The 3-phase armature windings will, in general, set up a third space harmonic of air-gap magnetomotive force which is stationary but pulsating. Currents will be induced in closed rotor circuits opposing this harmonic magnetomotive force and forcing the armature flux due to it into the low-permeance air-gap paths so that this reactance is indeed very small. The actual value depends greatly on winding pitch, being a minimum at $^2/_3$ pitch in a 3-phase winding. For at this pitch each slot contains coil sides of adjacent phases carrying currents in time phase but opposite direction. Consequently the net air-gap magnetomotive force of the slot is zero and the only flux produced in addition to end winding leakage is the slot leakage flux between the 2 conductors with opposite currents.

Plus signs indicate current entering plane of paper, minus signs—current leaving. Positive electromotive force in direction of positive current. Arrows indicate positive direction of flux or linkage or angle

**Figure 15. Conventions for positive angles, currents, electromotive forces, linkages, and rotation**

If zero-sequence currents be applied, the ratio of the phase linkage to phase current $\times\ \omega 10^{-8}$ gives zero-sequence reactance in ohms. This value divided by base ohms is $x_0$ in per unit.

Zero-sequence currents do not produce the same slot, end winding, or differential air-gap leakage fluxes as positive-sequence currents so that $x_l$ is not included in $x_0$.

The conditions used to define zero-sequence reactance are easily reproduced in an actual test, and if the machine were operated as described, the ratio of the voltage applied between the neutral and the 3 connected terminals to the current in one phase gives zero-sequence reactance in ohms.

## Summary

The various synchronous machine armature reactances have been discussed from a number of different viewpoints, each designed to enhance the physical picture: (1) linkage per ampere, (2) effective permeance, (3) a-c voltage per a-c ampere, (4) test and (5) figures illustrating the flux paths. The foregoing discussion is summarized in table I which gives the various pertinent factors influencing each reactance, and typical numerical values.

# Part III. Analytical Approach to Synchronous Machine Reactances

In the preceding parts a physical picture of certain arbitrary reactances has been built up. The uninitiated reader is, no doubt, in a quandary as to why these particular arbitrary definitions were selected. Furthermore, he is probably at a loss as to how to use such reactances in actual calculations of performance. It is not the purpose of this paper to present the whole of synchronous-machine analysis. However, the concepts of synchronous-machine reactance would be most incomplete without some idea as to their purpose and use. The following derivation is made from a most fundamental starting point and it will serve as a sound basis for proceeding with synchronous machine analysis as well as for broadening the physical picture already developed. Values of the various reactances are obtained in terms of the self- and mutual inductances of the various windings.

## Fundamental Synchronous Machine Parameters

It is proposed to set up the differential equations of the synchronous machine in terms of the fundamental parameters of the machine, the self- and mutual inductances of the various circuits.

The self-inductance of an armature phase depends upon the position of the rotor, being a maximum when the direct axis is lined up with the magnetic axis of the phase and a minimum when the quadrature axis is in line with it. The variation of the self-inductance between these 2 positions can be calculated from design data or it may be determined from tests. It is found by both means that the variation in practical machines is approximately sinusoidal as shown in figure 16. Since the maximum value will obtain whether the pole which is before the phase is normally north or normally south in magnetic polarity, the self-

inductance will vary through 2 maximum values if the rotor is rotated through 360 electrical degrees. Since it will have some positive value at every position of the poles, it will be of the form,

$$L_a = L_0 + M_0 \cos 2\phi \qquad L_0 > M_0 \tag{22}$$

where $L_0$ is the average and $M_0$ the amplitude of variation of the phase self-inductance in henries, ($M_0$ is not a mutual inductance as used here). $\phi$ is the electrical angle between the magnetic axis of the phase and the direct axis as shown in figure 15. This variation can be visualized by applying the concepts of part I to figure 15 and noting how the linkage per ampere of a phase varies as the rotor moves.

If $\phi$ be measured from the axis of phase $a$ then 22 gives the self-inductance of phase $a$, for at $\phi = 0$, $L_a$ is a maximum. Obviously, in a symmetrical machine, the self-

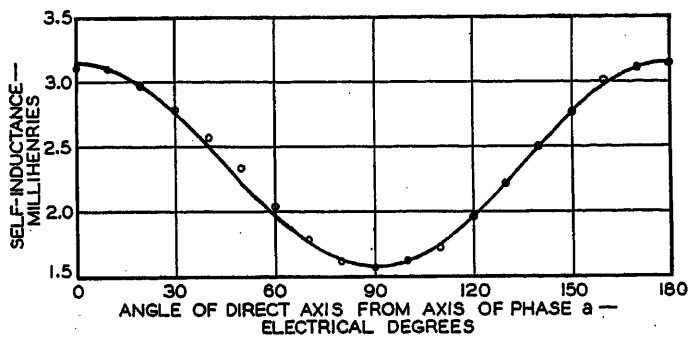


**Figure 16. Variation of self-inductance of armature phase a with position of the field**

The test points, taken on a 4-pole 15-kva 220-volt 1,800-rpm synchronous motor, compare favorably with the curve showing the theoretical variation of an ideal machine,

$$L_a = L_0 + M_0 \cos 2\phi = 2.36 + 0.796 \cos 2\phi \text{ (millihenries)}$$

inductance of each phase will have the same form except the maximum value will occur at a different value of $\phi$. That of phase $b$ will be a maximum when $\phi = 120$ electrical degrees,

$$L_b = L_0 + M_0 \cos 2(\phi - 120) = L_0 + M_0 \cos (2\phi + 120) \tag{23}$$

Likewise, the self-inductance of phase $c$ will be a maximum when $\phi = -120$ degrees,

$$L_c = L_0 + M_0 \cos 2(\phi + 120) = L_0 + M_0 \cos (2\phi - 120) \tag{24}$$

The mutual inductances between armature phases will also be functions of the rotor position. Positive currents are logically defined in the same relative direction in each of the phases as shown in figure 15. Thus, positive current in phase $b$ tends to produce linkage in phase $a$ in the opposite direction to that produced by positive current in phase $a$ (see figure 15). Hence, the sign of the mutual inductance between phases $a$ and $b$ is negative regardless of rotor position. The absolute magnitude of this mutual inductance will have a minimum value when the axis of the poles is midway between the phases (for phases $a$ and $b$, at $\phi = 60$ degrees), and a maximum value when the rotor has advanced 90 degrees from the position of minimum value. Hence, the mutual inductance between 2 phases also varies through 2 maximum values for a 360 degree rotation of the rotor. Experiments and calculations both show that the mutual inductance also varies approximately sinusoidally with $\phi$ as shown by the test on a particular machine in figure 17. Furthermore, experiments show that the amplitude of variation of mutual inductance in

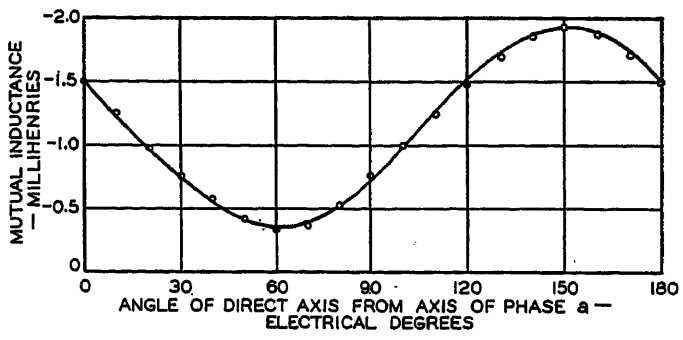

**Figure 17. Variation of mutual inductance between armature phases a and b with position of the field**

The test points taken on the same machine as in figure 16 are close to the curve which shows theoretical variation for an ideal machine

$$M_{ab} = -M_s + M_0 \cos (2\phi - 120°)$$
$$= -1.14 + 0.796 \cos (2\phi - 120°) \text{ millihenries}$$

practical machines is nearly the same as the amplitude of variation of self-inductance (see figures 16 and 17). Then, if $M_s$ is the average value of the mutual inductance between phases, the same $M_0$ used in equations 22, 23, and 24 is the amplitude of pulsation of the mutual inductance. Hence, the mutual inductance between phases $a$ and $b$ is

$$M_{ab} = -[M_s - M_0 \cos 2(\phi - 60)]$$
$$= -M_s + M_0 \cos (2\phi - 120) \qquad M_s > M_0 \tag{25}$$

Likewise, the minimum absolute magnitude of the mutual inductance between phases $b$ and $c$ will occur at $\phi = 0$ and

$$M_{bc} = -[M_s - M_0 \cos 2\phi] = -M_s + M_0 \cos 2\phi \tag{26}$$

Also

$$M_{ac} = -[M_s - M_0 \cos 2(\phi + 60)] = -M_s + M_0 \cos (2\phi + 120) \tag{27}$$

A complete analysis would, of course, include the effect of an arbitrary number of field circuits. However, the complexity of the equations which arise obscures the physical picture so that in this analysis no other rotor circuits except the main, direct-axis, field winding are assumed. Inspection of figure 15 shows that $M_d$, the maximum mutual inductance between phase $a$ and the main field winding will exist when the direct axis is in line with the magnetic axis of phase $a$, at $\phi = 0$, and its value will be equal but negative at $\phi = 180$ degrees. Test and calculation show that it varies approximately sinusoidally between these limits, so

$$M_{ad} = M_d \cos \phi \tag{28}$$

The mutual inductance between phase $b$ and the main field winding will have the same form but will be a maximum at $\phi = 120$ degrees, so

$$M_{bd} = M_d \cos(\phi - 120) \tag{29}$$

Likewise,

$$M_{cd} = M_d \cos(\phi + 120) \tag{30}$$

## Fundamental Synchronous Machine Equations

The assumptions which have been made are:

1. Saturation, hysteresis, and eddy currents are negligible.
2. Self- and mutual inductances vary sinusoidally as the rotor moves.

On the basis of the fundamental, experimental laws of Faraday, equation 1, and Ohm, the voltage, $e$, impressed on an armature phase may be expressed in terms of the phase resistance, $r$, phase linkage, $\psi$ and phase current $i$, in phase $a$ as

$$e_a = ri_a + \frac{d}{dt}\psi_a \times 10^{-8}$$

noting the time derivative operator, $d/dt$, by $p$,

$$e_a = ri_a + p\psi_a \times 10^{-8} \tag{31}$$

and for phases $b$ and $c$,

$$e_b = ri_b + p\psi_b \times 10^{-8} \tag{32}$$

$$e_c = ri_c + p\psi_c \times 10^{-8}* \tag{33}$$

A similar equation may be written for the main field winding in terms of its applied voltage $E_d$, current $I_d$, linkage $\Psi_d$ and resistance $R_d$.

$$E_d = R_d I_d + p\Psi_d \times 10^{-8} \tag{34}$$

Before these differential equations (31 to 34) can be solved for the currents in terms of the applied voltages it is necessary, of course, to express the linkages as functions of the currents in all circuits. Thus, from the definitions of self- and mutual inductance, equations 3 and 4, the linkage in phase $a$ is

$$\psi_a = \{L_a i_a + M_{ab} i_b + M_{ac} i_c + M_{ad} I_d\} 10^8$$

From equations 22, 25, 27, and 28,

$$\psi_a = \{i_a[L_0 + M_0 \cos 2\phi] + i_b[-M_s + M_0 \cos(2\phi - 120)] + i_c[-M_s + M_0 \cos(2\phi + 120)] + I_d M_d \cos\phi\} 10^8$$

$$\psi_a = \{L_0 i_a - M_s[i_b + i_c] + M_0[i_a \cos 2\phi + i_b \cos(2\phi - 120) + i_c \cos(2\phi + 120)] + I_d M_d \cos\phi\} 10^8 \tag{35}$$

Likewise, from equations 23, 25, 26, and 29,

$$\psi_b = \{L_0 i_b - M_s[i_c + i_a] + M_0[i_c \cos 2\phi + i_a \cos(2\phi - 120) + i_b \cos(2\phi + 120)] + I_d M_d \cos(\phi - 120)\} 10^8 \tag{36}$$

and from equations 24, 26, 27, and 30,

$$\psi_c = \{L_0 i_c - M_s[i_a + i_b] + M_0[i_b \cos 2\phi + i_c \cos(2\phi - 120) + i_a \cos(2\phi + 120)] + I_d M_d \cos(\phi + 120)\} 10^8 \tag{37}$$

If the main field winding self-inductance is $L_{fd}$—obviously it is a constant—the main field linkage may be expressed in terms of all currents by considering figure 15 and equations 28, 29, and 30

$$\Psi_d = M_{ad} i_a + M_{bd} i_b + M_{cd} i_c + L_{fd} I_d$$
$$= M_d[i_a \cos\phi + i_b \cos(\phi - 120) + i_c \cos(\phi + 120)] + L_{fd} I_d \tag{37a}$$

If equations 35, 36, 37, and 37$a$ are substituted in equations 31 to 34, the fundamental simultaneous differential equations of the synchronous machine will have been set up from Faraday's experimental law, equation 1, and measurable self- and mutual inductances.

Theoretically, the resulting differential equations can be solved simultaneously for the currents with any given applied voltages and motion of the rotor either in transient or steady state. However, if the rotor is moving, $\phi$ is a function of time. Consequently, when the differentiations indicated in equations 31 to 34 are performed, terms such as the following arise,

$$\frac{d}{dt}\left[M_0 i_b \cos(2\phi - 120)\right] =$$
$$-2M_0 i_b \sin(2\phi - 120)\frac{d\phi}{d} + M_0 \cos(2\phi - 120)\frac{di_b}{dt}$$

When the resulting differential equations are combined simultaneously to get a differential equation in terms of one of the currents only, a multitude of terms, even more complex than the one shown, arise which include functions of time—such as cose $2\phi$—as coefficients of the derivatives. The solution of these differential equations with variable coefficients as they stand is so difficult that it has never been carried out in a general case, and this is the reason for resorting to direct and quadrature axes, namely, in order to simplify the mathematics.

All are familiar with linear and nonlinear changes of variables in the calculus in order to simplify integration. Also, the change of co-ordinate axes such as from Cartesian to polar, or 3-dimensional Cartesian to spherical, etc., are nonlinear changes of variable, and rotation or translation of Cartesian reference axes are linear changes of variable which are commonplace. In the latter cases it is important to note that the number of degrees of freedom is not reduced and the new variables are independent of each other and related to the old ones by linear equations. Now if someone suggested that new, independent currents, flux linkages, etc., might be assumed, related to the old currents, flux linkages, etc., by linear equations which would facilitate the solution; we might throw up our hands in horror at this unorthodox procedure if we did not realize that the differential equations to be solved were really mathematical statements which can be manipulated at will so long as the fundamental rules of calculus, algebra, etc., are not violated. Consequently, it is sensible to take the view that the proposed transformation is a mathematical one and as long as it is eventually possible to return and find the old currents, linkages, etc., it is possible to proceed with confidence.

* This method of analysis is similar to that used by Park[12] except for different sign conventions, but is not the same as that used by Park[6] as it avoids the use of permeance coefficients. The sign conventions used here are those widely accepted in classical literature and were defined in part I.

Assume then, that someone has suggested the following new variables:

$i_d$, $\psi_d$, $e_d$—direct axis current, linkage, voltage

$i_q$, $\psi_q$, $e_q$—quadrature axis current, linkage, voltage

$i_0$, $\psi_0$, $e_0$—zero axis current, linkage, voltage

which are linearly related to the old variables by the equations,

$$\left.\begin{aligned} i_d &= \frac{2}{3}\left\{ i_a \cos\phi + i_b \cos(\phi - 120) + i_c \cos(\phi + 120) \right\} \\ i_q &= -\frac{2}{3}\left\{ i_a \sin\phi + i_b \sin(\phi - 120) + i_c \sin(\phi + 120) \right\} \\ {}_0 &= \frac{1}{3}\left\{ i_a + i_b + i_c \right\} \end{aligned}\right\} \quad (38)$$

and

$$\left.\begin{aligned} \psi_d &= \frac{2}{3}\left\{ \psi_a \cos\phi + \psi_b \cos(\phi - 120) + \psi_c \cos(\phi + 120) \right\} \\ \psi_q &= -\frac{2}{3}\left\{ \psi_a \sin\phi + \psi_b \sin(\phi - 120) + \psi_c \sin(\phi + 120) \right\} \\ \psi_0 &= \frac{1}{3}\left\{ \psi_a + \psi_b + \psi_c \right\} \end{aligned}\right\} \quad (39)$$

and

$$\left.\begin{aligned} e_d &= \frac{2}{3}\left\{ e_a \cos\phi + e_b \cos(\phi - 120) + e_c \cos(\phi + 120) \right\} \\ e_q &= -\frac{2}{3}\left\{ e_a \sin\phi + e_b \sin(\phi - 120) + e_c \sin(\phi + 120) \right\} \\ e_0 &= \frac{1}{3}\left\{ e_a + e_b + e_c \right\} \end{aligned}\right\} \quad (40)$$

Actually, these new variables were conceived and developed by engineers[1,2,3,4,5] by virtue of their very thorough and complete "physical picture" of the phenomena. For the present purpose, the physical picture and the physical reasoning back of the selection of such a set of transformations will be discussed after the results are obtained.

If the proposed change of variables enables solution of the equations, the actual physical phase currents, linkages, voltages, etc., can then finally be obtained from the following expressions for the phase quantities in terms of the new variables. Thus, solving simultaneously equations 38:

$$\left.\begin{aligned} i_a &= i_d \cos\phi - i_q \sin\phi + i_0 \\ {}_b &= i_d \cos(\phi - 120) - i_q \sin(\phi - 120) + i_0 \\ i_c &= i_d \cos(\phi + 120) - i_q \sin(\phi + 120) + i_0 \end{aligned}\right\} \quad (41)$$

and equations 39:

$$\left.\begin{aligned} \psi_a &= \psi_d \cos\phi - \psi_q \sin\phi + \psi_0 \\ \psi_b &= \psi_d \cos(\phi - 120) - \psi_q \sin(\phi - 120) + \psi_0 \\ \psi_c &= \psi_d \cos(\phi + 120) - \psi_q \sin(\phi + 120) + \psi_0 \end{aligned}\right\} \quad (42)$$

* A hint to the student in solving, say, equations 40 to obtain equations 43 is to multiply the first one of equations 40 by cos $\phi$, the second by $-$ sine $\phi$ and add. The trigonometric coefficients of $e_b$ and $e_c$ can be shown to be zero, that of $e_a$ unity which gives a ready solution for $e_a$ in terms of $e_d$, $e_q$, and $e_0$. Similar operations yield $e_b$ and $e_c$.

and equations 40:

$$\left.\begin{aligned} e_a &= e_d \cos\phi - e_q \sin\phi + e_0 \\ e_b &= e_d \cos(\phi - 120°) - e_q \sin(\phi - 120°) + e_0 \\ e_c &= e_d \cos(\phi + 120°) - e_q \sin(\phi + 120°) + e_0* \end{aligned}\right\} \quad (43)$$

Now to proceed with the change of variable. Substitute equations 38 in equations 35, 36, and 37. Combine the resulting expressions for $\psi_a$, $\psi_b$, and $\psi_c$ according to equations 39 to get $\psi_d$, $\psi_q$, and $\psi_0$ wholly in terms of $i_d$, $i_q$, $i_0$ the self- and mutual inductances and trigonometric expressions. The algebra and trigonometry of these transformations are formidable but if the student has sufficient fortitude he will find that the many multiple products of trigonometric functions are all reducible to single simple constants and he will be rewarded by the following very simple equations:

$$\psi_d = \left\{ M_d I_d + \left( L_0 + M_s + \frac{3}{2} M_0 \right) i_d \right\} 10^8 \quad (44)$$

$$\psi_q = \left\{ \left( L_0 + M_s - \frac{3}{2} M_0 \right) i_q \right\} 10^8 \quad (45)$$

$$\psi_0 = \left\{ (L_0 - 2M_s) i_0 \right\} 10^8 \quad (46)$$

These expressions are relations between the new variables, linkages, and currents, in the direct, quadrature, and zero axes. Note that each equation contains only variables in the same axis. Mathematically this means that the choice of new variables has been particularly appropriate and that the equations will be relatively simple to solve in terms of the new variables.

Now each equation physically is a relation between currents and linkage and the factors of proportionality are constants. Consequently it requires only a little imagination to see that the bracketed constants of proportionality are really equivalent inductances in the new system of variables. Furthermore, it is natural to suspect that the constant of proportionality in equation 44 is the inductance corresponding to direct synchronous reactance $x_d$, that of equation 45 to $x_q$, and that of equation 46 to $x_0$. That this is true can be proved quickly by applying the conditions defining these reactances in part II to equation 35, and finding the linkage in phase $a$, $\psi_a$, per unit current in phase $a$, $i_a$. Either of the other phases might be used.

## Direct Synchronous Reactance $x_d$

The conditions specified are:

1. Positive-sequence steady-state currents applied to the armature

$$\left.\begin{aligned} i_a &= i \cos \omega t \\ i_b &= i \cos(\omega t - 120) \\ i_c &= i \cos(\omega t + 120) \\ &\text{and} \\ i_b &+ i_c = -i_a \end{aligned}\right\} \quad (46a)$$

2. Field circuit open,

$$I_d = 0$$

3. Field rotated at constant synchronous speed so that the direct axis is in line with the axis of the armature magnetomotive-force wave,

$\phi = \omega t$

Substitute these conditions in equation 35.

$$\psi_a = \{i \cos \omega t\,(L_0 + M_s) + M_0 i\,[\cos \omega t \cos 2\omega t + \cos(\omega t - 120) \times \cos(2\omega t - 120) + \cos(\omega t + 120)\cos(2\omega t + 120)]\}10^8$$

which, upon trigonometric reduction becomes

$$\psi_a = \left[\left(L_0 + M_s + \frac{3}{2}M_0\right) i \cos \omega t\right] 10^8$$

$$= \left(L_0 + M_s + \frac{3}{2}M_0\right) i_a \times 10^8$$

and as defined, $x_d$ in ohms is the armature linkage per armature ampere times $\omega\, 10^{-8}$ so

$$x_d = \frac{\psi_a}{i_a}\omega\, 10^{-8} = \left(L_0 + M_s + \frac{3}{2}M_0\right)\omega \qquad (47)$$

## Quadrature Synchronous Reactance $x_q$

The conditions specified are:

1 and 2 are the same as under $x_d$.

3. Field rotated at constant speed so that the quadrature axis is in line with the axis of the armature magnetomotive-force wave,

$\phi = \omega t - 90°$*

Then equation 35 becomes

$$\psi_a = \{i \cos \omega t\,(L_0 + M_s) + M_0 i[\cos \omega t \cos 2(\omega t - 90) + \cos(\omega t - 120)\cos\{2(\omega t - 90) - 120\} + \cos(\omega t + 120)\cos\{2(\omega t - 90) + 120\}]\}10^8$$

$$= \{i \cos \omega t\,(L_0 + M_s) - M_0 i[\cos \omega t \cos 2\omega t + \cos(\omega t - 120)\cos(2\omega t - 120) + \cos(\omega t + 120)\cos(2\omega t + 120)]\}10^8$$

which, by comparison with the previous example is

$$\psi_a = \left(L_0 + M_s - \frac{3}{2}M_0\right) i \cos \omega t \times 10^8$$

and

$$x_q = \left(L_0 + M_s - \frac{3}{2}M_0\right)\omega \qquad (48)$$

## Zero-Sequence Reactance $x_0$

The conditions specified are:

1. Zero-sequence, steady-state currents applied to the armature,

$i_a = i_b = i_c = i \cos \omega t$

2. Effect of field circuits, negligible,

$I_d = 0$

3. Motion of the rotor immaterial as will be evident,

$\phi = \phi$

* The sign is negative because the usual convention is to designate the interpolar space *ahead* of the poles as the quadrature axis. This is explicitly required by the signs in equations 38, 39, and 40.

Equation 35 becomes,

$$\psi_a = \{i \cos \omega t\,[L_0 - 2M_s] + M_0 i \cos \omega t\,[\cos \phi + \cos(\phi - 120) + \cos(\phi + 120)]\}10^8$$

The last term is obviously zero regardless of how $\phi$ varies, so

$$\psi_a = \{[L_0 - 2M_s] i \cos \omega t\}10^8$$

and

$$x_0 = (L_0 - 2M_s)\omega \qquad (49)$$

Equations 44, 45, and 46 then become,

$$\left.\begin{aligned} \psi_d &= \left[M_d I_d + \frac{x_d i_d}{\omega}\right]10^8 \\ \psi_q &= \frac{x_q i_q}{\omega} \times 10^8 \\ \psi_0 &= \frac{x_0 i_0}{\omega} \times 10^8 \end{aligned}\right\} \qquad (50)$$

## Machine Equations in the Direct, Quadrature, and Zero Axes

Before deriving an expression for $x_d'$ the machine equations in terms of the direct-, quadrature-, and zero-axis quantities will be determined. They will then be employed to obtain $x_d'$ to illustrate the use of these equations rather than using the method just applied to get $x_d$, $x_q$, and $x_0$. The following derivation was given by Park[6] with different sign conventions. Combining the fundamental phase voltage equations 31, 32, and 33 with the definition of $e_d$, equation 40,

$$e_d = \frac{2}{3}\left\{\cos\phi\,(ri_a + p\psi_a \times 10^{-8}) + \cos(\phi - 120) \times (ri_b + p\psi_b \times 10^{-8}) + \cos(\phi + 120)(ri_c + p\psi_c \times 10^{-8})\right\}$$

and the definition of $i_d$, equation 38, allows a reduction to

$$e_d = ri_d + \frac{2}{3}\left\{\cos\phi\, p\psi_a + \cos(\phi - 120)\, p\psi_b + \cos(\phi + 120) p\psi_c\right\} \times 10^{-8} \qquad (51)$$

The bracketed term is unfamiliar; however, differentiate $\psi_d$, equation 39,

$$p\psi_d = \frac{2}{3}\left\{\cos\phi\, p\psi_a + \cos(\phi - 120)\, p\psi_b + \cos(\phi + 120) p\psi_c\right\} - \frac{2}{3}\left\{\psi_a \sin\phi + \psi_b \sin(\phi - 120) + \psi_c \sin(\phi + 120)\right\} p\phi \qquad (52)$$

The first bracketed term of this expression is identical with the bracketed term in equation 51. However, the last bracketed term in equation 52 is, by comparison with the

definition of $\psi_q$, equation 39, $\psi_q p\phi$. Therefore the bracketed expression in equation 51 is

$$p\psi_d - \psi_q p\phi$$

and

$$\left.\begin{aligned} e_d &= ri_d + (p\psi_d - \psi_q p\phi)10^{-8} \\ &\text{By similar substitutions Park}^6 \text{ shows that} \\ e_q &= ri_q + (p\psi_q + \psi_d p\phi)10^{-8} \\ &\text{and} \\ e_0 &= ri_0 + p\psi_0 \times 10^{-8} \end{aligned}\right\} \quad (53)$$

Now, $\psi_d$, $\psi_q$, and $\psi_0$ are known in terms of currents and measurable reactances, equations 50. Consequently, equations 50, 53, and 34 may be used to solve for $i_d$, $i_q$, $i_0$, and $I_d$ if the applied voltages $e_d$, $e_q$, $e_0$, and $E_d$ are known, and the motion of the rotor is known. The phase currents may then be obtained from equations 41. This is one of the first steps in a complete method of synchronous machine analysis as given by Park.[6]

## Direct Transient Reactance $x_d'$

The conditions used to define direct transient reactance were:

1. Positive-phase-sequence currents suddenly applied to the armature, expressions for which are given in equation 46*a*.
2. Field circuit closed, not excited. By the constant linkage law.

$$\Psi_d = 0$$

3. Field rotated at constant speed so that the direct axis is in line with the peak of newly established armature magnetomotive-force wave.

$$\phi = \omega t$$

If conditions 1 and 3 be put in equation 38, the direct-, quadrature-, and zero-axis currents as functions of time are found to be

$$i_d = i$$

$$i_q = 0$$

$$i_0 = 0$$

Comparison of equation 50 with condition 1 shows that

$$\psi_d = \left[ M_d I_d + \frac{x_d}{\omega} i_d \right] 10^8 \quad (54)$$

$$\psi_q = 0$$

$$\psi_0 = 0$$

Comparing equation 37*a* with $i_d$ in equation 38 shows that

$$\Psi_d = L_{fd} I_d + \frac{3}{2} M_d i_d \quad (55)$$

which gives a ready solution for $I_d$ on application of condition 2, thus

$$I_d = -\frac{3}{2}\frac{M_d}{L_{fd}} i_d$$

Then, equation 54 gives $\psi_d$ in terms of $i_d$

$$\psi_d = \left[ \frac{x_d}{\omega} - \frac{3}{2}\frac{M_d^2}{L_{fd}} \right] i_d \, 10^8 \quad (56)$$

Since $\psi_q = \psi_0 = i_q = i_0 = 0$, equations 41 and 42 show that

$$\frac{\psi_a}{i_a} = \frac{\psi_d}{i_d}$$

Therefore, the armature linkage per armature ampere under this condition is

$$\frac{\psi_d}{i_d} = \left[ \frac{x_d}{\omega} - \frac{3}{2}\frac{M_d^2}{L_{fd}} \right] 10^8 = \left[ L_0 + M_s + \frac{3}{2} M_0 - \frac{3}{2}\frac{M_d^2}{L_{fd}} \right] 10^8$$

and the direct transient reactance is

$$\left.\begin{aligned} x_d' &= \frac{\psi_a}{i_a}\omega \, 10^{-8} = \left[ L_0 + M_s + \frac{3}{2} M_0 - \frac{3}{2}\frac{M_d^2}{L_{fd}} \right]\omega \\ &= x_d - \frac{3}{2}\frac{M_d^2}{L_{fd}}\omega \end{aligned}\right\} \quad (57)$$

The similarity between the expression for $x_d'$ and the short-circuit transformer leakage reactance equation 19 is striking.

$$x_{sc} = \omega L_1 - \frac{M'^2}{L_2'}\omega \quad (19)$$

The analogy is obvious. Recall, for instance that the physical argument used in part II in discussing $x_d'$ which was based on short-circuit transformer phenomena. The presence of the $^3/_2$ may be physically explained on the basis that all 3 phase currents contribute to the armature magnetomotive force attempting to establish flux in the field, whereas in the transformer only one primary coil was excited, however, space does not permit going through this interesting physical argument. Nevertheless, it is strongly recommended that the student make thoroughgoing physical explanations of the presence of the various terms in the equations for $x_d$, $x_q$, $x_0$, and $x_d'$. Such a task will both require and greatly enhance the physical picture of the synchronous machine.

## Per-Unit Quantities

In previous literature, mathematical developments such as given here have been carried out in the per-unit system even in literal form. In more complete derivations such procedure has advantage in the resulting simplicity of equations. However, for one not thoroughly familiar with the per-unit system, the nonhomogeneous appearance of equations is confusing. Consequently, in this educational paper, the derivations have been presented in classical notation, it being inadvisable to present 2 new viewpoints simultaneously. All equations in part III can be converted to equations in a consistent per-unit system simply by omitting all $\omega$'s, $10^8$'s, and $10^{-8}$'s.

The major value of the per-unit system lies in numerical work. If one has solved a problem for a typical machine in per unit, the results apply to any size or rating of ma-

chine with similar per-unit parameters. Furthermore, the numbers in a per-unit calculation are of convenient size and the engineer can check their approximate values from experience and physical reasoning, thus reducing the chance for error.

## Physical Picture

The final phase of the physical picture, which this paper attempts to build up, may now be developed from equations 53. We seek a concept of the fictitious direct-, quadrature-, and zero-axis windings which give rise to the rather unusual equations 53. The equations are unusual because of the presence of the $\psi_d p\phi$ and $\psi_d p\phi$ terms, the like of which do not occur in equations for the electromotive force in a circuit fixed in the observer's initial system.

Let us as observers, reside upon the rotating field structure and attempt to visualize the phenomena experienced in the direct axis. The armature phase currents, assumed to be positive phase sequence for this visualization, will produce a rotating sinusoidal magnetomotive-force wave which may be resolved into 2 space sinusoidal components, one in line with the direct axis, the other with the quadrature axis. The absolute and relative magnitudes of the components may, of course, vary with time. Now visualize a winding opposite the direct axis and rotating with it which has the same resistance as an armature phase, $r$. If this winding carried a current $i_d$ it would produce a magnetomotive force in the direct axis, and $i_d$ might be such a function of time that its magnetomotive force was always equal to the direct axis component of the magnetomotive force produced by phase currents. For instance, if *steady-state*, positive-sequence armature currents flowed, $i_d$ would be direct current, producing a constant magnetomotive force in the direct axis. The voltage equation of such a fictitious winding would be, by Faraday's and Ohm's laws,

$$e_d = ri_d + p\psi_d \times 10^{-8}$$

for $\psi_d$ is the component of armature linkage opposite the direct axis. But, this physical picture is not complete because of the absence of $\psi_q p\phi$. The reason is that we have attempted to replace a symmetrical series of armature windings moving past the field pole and relative to the observer with a velocity $p\phi$ by one *ordinary* winding stationary with respect to the field poles. Now note that the *sides* of the fictitious direct-axis winding lie in the quadrature axis and in a flux density proportional to $\psi_q$. If these sides of the winding are imagined to have an instantaneous velocity $p\phi$ relative to the poles and the observer, then they would have a motional electromotive force induced due to motion relative to the observer proportional to $\psi_q p\phi$, and, if the fictitious winding is chosen properly and $\psi_q$ is positive ahead of the poles, equal to $-\psi_q p\phi$. The resulting equation would then be

$$e_d = ri_d + (p\psi_d - \psi_q p\phi)10^{-8}$$

The complete physical picture of the fictitious direct-axis winding is, then, a winding, similar to an armature phase, moving with the speed of the poles so that its magnetic axis is always in line with the direct axis, but *extraordinary* to the extent that its coil sides have an instantaneous velocity relative to the field poles of $p\phi$. Study will show that this is equivalent to a commutated winding like, for instance, the armature winding of a d-c motor when viewed from the field poles. Furthermore, the motional voltage cannot be attributed to a velocity through flux for the flux is produced by the combined action of the moving field poles and stationary armature conductors.

Obviously the physical picture of the fictitious quadrature-axis winding is identical with that for the direct axis, except for location. The term $\psi_d p\phi$ appears with a positive sign since positive direct-axis linkage is "behind" the quadrature axis.

The physical picture of a zero-axis winding is unimportant. It may be a 3-phase winding, stationary on the armature, connected as described in part II under "Zero-Sequence Reactance."

## Summary and Recommendation to Students

It is important to recall that the references, mentioned in the introduction and throughout the paper, furnish the basis for this paper. Part I is a presentation of the fundamental concepts of inductance such as has been developed and clarified in the advanced course in engineering[14] of the General Electric Company by many lecturers. Part II includes the viewpoints presented by Shildneck,[12] some of the tests given by Park and Robertson,[9] and some ideas not heretofore published. Part III incorporates methods similar to those used by Park,[13] but with considerable emphasis on the physical picture.

This paper has been written specifically to bridge the gap existing between collegiate study and current synchronous-machine literature. Hence, it is appropriate to suggest a program to the student for further study leading to the actual analysis. The program suggested is essentially that which has been used in the $B$-class, electrical engineering section of the advanced course in engineering in training graduates, one year out of college. A knowledge of differential equations such as given by Doherty and Keller[15] is necessary, and a knowledge of operational calculus[15] is desirable before proceeding far in the program.

1. Reference 1 gives the theoretical proof of validity of direct- and quadrature-axis representation and a study of it gives an excellent physical picture of the actual fluxes, linkages, currents, etc., in the machine.

2. The student may then proceed directly to references 5 and 6 and study and use, the complete, powerful, analytical methods presented by Park therein. These references are extremely concise and considerable thinking will be required of the student to follow the analysis and extend it to new problems. However, the more thinking required the better will be his ultimate understanding. Either sign conventions may be employed. Those used in this paper probably agree with the students' previous training.

3. Concurrently with the study just recommended references 7, 8, and 9 should be used to extend the students'

knowledge of reactances and references 2, 3, and 4 should be studied when working any of the specific types of problems therein, to aid in forming a very clear, complete physical picture of the phenomena; a very important phase.

4. Having mastered the preceding ideas and methods, the student should be able to solve a large number of synchronous machine problems, granting sufficient engineering and mathematical ingenuity and available time, on the assumption of no saturation, hysteresis, or eddy currents. Then he may proceed with the more recent literature on the extensions of the theory and its associated reactances.

It should not be inferred from this paper that synchronous-machine problems are all of standard type, and solvable by standard methods. Quite to the contrary, new problems are arising all of the time which require analysis directly from fundamentals. For example, a few such problems which have become important recently are:

1. The effects of saturation on both steady-state and transient performance. In some cases the effect of saturation is even more pronounced than the effect of saliency.

2. The effects of eddy currents in the solid cylindrical rotor of turbine generators during transient conditions, mentioned in part II.

3. Analysis of phenomena contingent to internal faults in the machine. This problem involves analysis with nonsymmetrical windings; additional complications arise due to dissymmetry, not only between phases but between the various pairs of poles on the armature and field.

4. Determination of reactances and performance of large double-winding generators.

5. Determination of performance with external capacitance. This problem requires an extension of the 2-reaction theory such as given by Crary.[20]

As such novel problems are frequently of great consequence and a recourse to fundamentals is necessary for their solution, the paramount importance of a thorough knowledge of the fundamentals and their associated physical picture cannot be overemphasized.

## Nomenclature

### Subscripts

$a$, $b$, and $c$ refer to armature phases $a$, $b$, and $c$ of a machine.
$d$, $q$, and 0 refer to direct-, quadrature-, and zero-axis quantities.

### Notation

$i$ = current, amperes
$I_d$ = direct-axis main-field-winding current, amperes
$e$ = electromotive force, volts
$E_d$ = direct-axis main-field-winding electromotive force, volts
$\psi$ = flux linkage, lines times turns
$\Psi_d$ = direct-axis main-field-winding linkage, lines times turns
$L$ = self-inductance, henries
$L_0$ = average value of phase self-inductance, henries
$L_{fd}$ = direct-axis main-field-winding self-inductance, henries
$l_{oc}$ = open-circuit leakage inductance, henries
$l_{sc}$ = short-circuit leakage inductance, henries
$l_B$ = bucking leakage inductance, henries
$M$ = mutual inductance, henries
$M_0$ = amplitude of variation of phase self-inductance and of mutual inductance between phases, henries
$M_d$ = mutual inductance between the armature and the direct-axis main-field winding, henries
$M_s$ = average value of mutual inductance between phases, henries
$\phi$ = angle between the direct axis and the axis of phase $a$
$\omega$ = rated angular frequency = $2\pi f$ radians per second
$f$ = rated frequency, cycles per second
$t$ = time, seconds
$p$ = time derivative operator = $\frac{d}{dt}$
$\mathcal{P}$ = permeance
$x_l$ = armature leakage reactance
$x_d$ = direct synchronous reactance
$x_q$ = quadrature synchronous reactance
$x_d'$ = direct transient reactance
$x_d''$ = direct subtransient reactance
$x_q'$ = quadrature transient reactance
$x_q''$ = quadrature subtransient reactance
$x_2$ = negative-sequence reactance
$x_0$ = zero-sequence reactance

# Per-Unit Quantities

By IRVEN TRAVIS
ASSOCIATE AIEE

## Summary

This paper discusses the use of per-unit quantities and their relation to dimensional analysis. It has been written at the request of the committee on education, and designed primarily for those interested in education, to serve as a background for discussion of the need which has arisen in the electrical engineering literature to translate new techniques into language readily understandable by students.

The use of per-unit quantities in the current machinery literature, although invaluable to the practicing engineer who wishes to obtain as much similarity as possible in calculations of machines and transformers of various ratings, is confusing to the average student, largely because factors which have physical significance are divided out and dimensions which would aid him in recognizing the origin of the different terms in an equation disappear.

IN THE electrical machinery field there has been for the last several years an increasing gap between the theoretical training given in the average engineering school and that required by industry. The accounts of recent developments, particularly in synchronous-machine theory, short-circuit calculations, and power-system stability, are not easy for the senior student in electrical engineering or even the young graduate to follow. The result has been that there is at present a wealth of technical literature in this field which is read by a small minority. The same condition, probably to a lesser degree, exists in the other fields.

It is felt that articles which supply fundamental theory not ordinarily given in undergraduate courses and which correlate the important developments during the past 10 years would greatly increase the value of a vast amount of literature now available only to a few.

The above remarks represent an untested opinion. The publication of this paper is an experiment. The AIEE committee on education and the author welcome comments from the membership both in regard to the general aims and to this paper specifically.

## Definition and Advantages of Per-Unit Quantities

The concept of per-unit quantity is by no means restricted to the field of electrical engineering; although the *term* is not usually employed elsewhere. For example, an infantry officer would hardly say "increase cadence to 240 steps per minute" but is accustomed to give the command "double time!" "Double time" may be regarded as a per-unit speed of 2 to the base 120 steps per minute; the latter being normal or unit speed.* Any system in which quantity is expressed as the multiplying factor of some normal value, rather than in the usual units for the quantity being expressed, is called a *per-unit* system. The ordinary percentage system is a per-unit system. Here the base is 100 per cent, consequently a given percentage value is 100 times the equivalent per-unit value.

In accordance with the above, currents, voltages, resistances, etc., may be expressed in per-unit values. A per-unit current of 2 means that the current under consideration is twice some preassigned current which has been designated as the base or unit current. It is convenient in most engineering work to use the normal rated value of a given quantity as the base to which the per-unit value of that quantity is referred. If this is done a per-unit current of 3 is immediately recognizable as a dangerous overload. From a practical viewpoint this means more than to specify the current as, say, 50 amperes, since the latter implies nothing at all about the propriety of allowing such a condition to exist.

A further advantage of expressing quantities in per unit is that measurements or calculations made on one of several similar devices are then immediately applicable to the others of the group by simply changing the base value.

A still greater advantage accrues from the fact that troublesome factors which appear in the normal quantity disappear when it is expressed in per unit. For example, the self-inductance of a coil is given by

$$L = 4\pi N^2 10^{-9} \mathcal{P} \text{ henrys} \qquad (1)$$

where $N$ is the number of turns and $\mathcal{P}$ is the permeance, in centimeter-gram-second units, of the flux path. If some value of the inductance be assumed as normal, or unit value, and if the inductance throughout a given set of calculations can change only due to changing permeance then we have

$$L(\text{per unit}) = \frac{4\pi N^2 10^{-9} \mathcal{P}}{4\pi N^2 10^{-9} \mathcal{P}\ (\text{normal})} = \mathcal{P}\ (\text{per unit}) \qquad (2)$$

Thus it may be possible to calculate a per-unit self-induced electromotive force without ever inquiring into the question of the number of turns involved. Such principles can actually be put to use in electric-circuit and electric-machine calculations.

## Application to Simple Equations

Although it is obviously possible to express all quantities relating to a given problem in per unit, it is not at all

A paper recommended for publication by the AIEE committee on education. Manuscript submitted October 17, 1936; released for publication May 24, 1937, by the AIEE board of directors for publication in pamphlet form and as a supplement to the 1937 TRANSACTIONS.

IRVEN TRAVIS is assistant professor of electrical engineering at the Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia.

* The writer has taken a certain liberty here with military terminology, actually "double time" means approximately "1.5 time."

obvious that the per-unit quantities will satisfy the same equations as the quantities from which they were derived. As a matter of fact they will not satisfy such equations unless the bases are chosen in a particular manner. This will be illustrated by simple examples.

EXAMPLE I

The voltage drop in a circuit containing resistance only is

$$v = ri \tag{3}$$

In this equation $r$ and $i$ may be considered independent variables and $v$ the dependent variable. Suppose it be desired to express this equation in per-unit form. It will be necessary to use some value of current, preferably the rated current $I_0$ as the base or unit current and some value of resistance $R_0$ as the base or unit resistance. Thus

$$I_{pu} = i/I_0 \tag{4}$$

and

$$R_{pu} = r/R_0 \tag{5}$$

If it is required that the per-unit current and resistance satisfy Ohm's law then the per-unit voltage associated with them is given by

$$V_{pu} = R_{pu}I_{pu} = \frac{ri}{R_0I_0} = \frac{v}{R_0I_0} \tag{6}$$

hence the per-unit voltage *must* be expressed as

$$V_{pu} = v/V_0 \tag{7}$$

where $V_0$ is the base voltage defined by

$$V_0 = R_0I_0 \tag{7a}$$

Let $v$, $r$, and $i$ be variables related as in equation 3 and let the unit or base value of $r = 10$ ohms, of $i = 15$ amperes, then the unit or base value of $v = 150$ volts. Suppose $r$ is changed to 15 ohms, then $R_{pu} = 1.5$, and if $i$ is changed to 30 amperes, then $I_{pu} = 2$. Now $V_{pu} = R_{pu}I_{pu} = 3$. Since the base of $v$ is 150 volts the new value of $v$ is 450 volts.

This example suggests that, although the bases may not all be specified independently, the rules for specifying them are relatively simple. Let us look at another example.

EXAMPLE II

The voltage drop in a circuit containing resistance and self-inductance is given by

$$v = ri + L\frac{di}{dt} \tag{8}$$

Let us express all quantities on the right-hand side in per unit and attempt to calculate the base voltage which must be used on the left-hand side of the equation.

$$V_{pu} = \frac{r}{R_0}\frac{i}{I_0} + \frac{L}{L_0}\frac{d\left(\frac{i}{I_0}\right)}{d\left(\frac{t}{T_0}\right)} = \left(\frac{1}{R_0I_0}\right)ri + \left(\frac{T_0}{L_0I_0}\right)\frac{di}{dt} \tag{9}$$

In order to make this equation agree with equation 8 we must divide out the coefficients on the right-hand side of the equation. This cannot be done unless

$$\frac{1}{R_0I_0} = \frac{T_0}{L_0I_0} \tag{10}$$

Making use of equation 10 we find that the base voltage must be chosen as

$$V_0 = R_0I_0 \tag{7a}$$

which agrees with example I.

It is easy to see why equation 10 must be satisfied. Both of the terms on the right-hand side of equation 8 have the dimensions of volts; therefore they must both be represented to the same scale. In writing down equation 9 we attempted to assign arbitrary values to too many base quantities. From equation 10 it is evident that if $L_0$ and $R_0$ are assigned then

$$T_0 = \frac{L_0}{R_0} \tag{11}$$

This is not surprising in view of the fact that inductance divided by resistance has the dimensions of time.

Thus we see that of the 5 base quantities ($V_0$, $I_0$, $R_0$, $L_0$, $T_0$) necessary to express equation 8 in per unit only 3 may be specified independently. The other 2 are then determined by equations 7*a* and 11. These equations must be satisfied in order that the scales for each of the fundamental units throughout the equation may be consistent. In other words the dimensional relations of units must be taken into account since the equations are dimensional equations.

The following numerical example serves as a further illustration of the system: Let $r = 20$ ohms, $L = 0.03$ henry, and $i = 5\sqrt{2}$ sine $377t$. Then in ordinary units the equation 8 is

$$v = 20 \times 5\sqrt{2}\sin 377t + 0.03 \times 5\sqrt{2}\frac{d}{dt}(\sin 377t) = 115\sqrt{2}\sin(377t + 30°)$$

Let unit time be chosen as the number of seconds per radian in the sine wave, then $T_0 = 1/377$. Let unit current be chosen as $I_0 = 5\sqrt{2}$ and unit voltage as $V_0 = 115\sqrt{2}$, then unit resistance and unit inductance are given by

$$R_0 = \frac{V_0}{I_0} = 23$$

$$L_0 = R_0T_0 = 0.061$$

In per-unit terms we have

$$R_{pu} = 0.87 \qquad L_{pu} = 0.49 \qquad I_{pu} = \sin T_{pu}$$

and since the per-unit quantities satisfy equation 8 we have

$$V_{pu} = 0.87\sin T_{pu} + 0.49\frac{d}{dT_{pu}}(\sin T_{pu}) = \sin(T_{pu} + 30°)$$

## Dimensions of Electrical Quantities

From the above it is evident that it is not possible to assign mutually consistent base values for the calculation of

**Table I**

| Quantity | Exponents in Dimensional Formula L | M | T | Q | MKS Unit |
|---|---|---|---|---|---|
| Length | 1 | 0 | 0 | 0 | Meter |
| Mass | 0 | 1 | 0 | 0 | Kilogram |
| Time | 0 | 0 | 1 | 0 | Second |
| Quantity of electricity | 0 | 0 | 0 | 1 | Coulomb |

*Rationalized units only given, see reference 10.

per-unit quantities without first investigating the dimensional nature of the equations at hand.

If per-unit quantities are to be used in equations involving mechanical quantities, such as torque, moment of inertia, etc., as well as electrical quantities, it is not sufficient to investigate the electrical dimensions of the quantities. All physical quantities involved must be broken down into their dimensions in terms of fundamental units such as length, mass, etc.; since only in this way can it be assured that electrical and mechanical entities are represented to the same scale.

The dimensions of electrical quantities in terms of the fundamental units length, mass, and time are not uniquely defined.[16] Historically the centimeter-gram-second (cgs) electromagnetic and the cgs electrostatic systems have been the most generally used. In the cgs electromagnetic system of units, the units are derived from mechanical forces observed to be exerted on the poles of a suspended magnet, on the assumption that the permeability of free space may be taken to be dimensionless. In the cgs electrostatic system, the units are derived from the mechanical forces observed to be exerted on suspended electric charges, on the assumption that the dielectric constant of free space may be taken to be dimensionless. In 1881 Maxwell showed that the product of the permeability ($\mu$) and the dielectric constant ($k$) of free space had the dimensions of slowness squared, i.e., (seconds per centimeter).[2] Depending upon the choice of dimensions for $\mu$ (or $k$), infinitely many consistent systems of dimensions can be set up for the various electric and magnetic quantities.

Electric current, for example, may be expressed dimensionally as

$$i = L^{1/2}M^{1/2}T^{-1}\mu^{-1/2} \tag{12}$$

or, since $\mu = k^{-1}L^{-2}T^2$, as

$$i = L^{3/2}M^{1/2}T^{-2}k^{1/2} \tag{13}$$

In the electromagnetic system, since $\mu$ is assumed to be dimensionless, equation 12 becomes

$$i = L^{1/2}M^{1/2}T^{-1} \tag{12a}$$

whereas in the electrostatic system, since $k$ is assumed to be dimensionless, equation 13 becomes.

$$i = L^{3/2}M^{1/2}T^{-2} \tag{13a}$$

It is apparent that (12$a$) and (13$a$) are inconsistent.

The present viewpoint is that a fourth fundamental dimension should be used. It appears that either electric charge or electric current would be the most convenient of the electrical quantities and it is likely that one of these will ultimately be adopted.[10] In this paper quantity of electricity will be taken as the fourth fundamental dimension. Table I gives the exponents in the dimensional formulas for various mechanical and electrical quantities. In accordance with the present international standard, the meter-kilogram-second (mks) system of units is given in the table.

## A Theorem in Dimensional Analysis

The following general principles derivable from the theory of dimensional analysis yield all necessary rules for the selection of base values for per-unit quantities.

Suppose a given quantity $x_1$ to be expressed by the equation

$$f(x_1, x_2, x_3, \ldots, x_n) = 0 \tag{14}$$

in which the quantities $x_2, x_3, \ldots, x_n$ are independent variables or parameters having physical dimensions; then $x_1$ will also have physical dimensions. For example equation 8 is of the form

$$f(v, r, i, L, t) = 0 \tag{14a}$$

Let it be desired to express all of the $x$'s in per unit and let it be required that the per-unit values satisfy equation 14. If the bases are represented by $B_1$, $B_2$, $B_3$, etc., equation becomes

$$f\left(\frac{x_1}{B_1}, \frac{x_2}{B_2}, \frac{x_3}{B_3}, \ldots, \frac{x_n}{B_n}\right) = 0 \tag{15}$$

Since each of the $x$'s represents a physical quantity having dimensions each may be written as a dimensionless factor times its dimensions.[3] Thus

$$\left.\begin{aligned} x_1 &= X_1L^{\alpha_{1l}}M^{\alpha_{1m}}T^{\alpha_{1t}}Q^{\alpha_{1q}} \\ x_2 &= X_2L^{\alpha_{2l}}M^{\alpha_{2m}}T^{\alpha_{2t}}Q^{\alpha_{2q}} \\ &\cdots\cdots\cdots\cdots\cdots\cdots \\ x_n &= X_nL^{\alpha_{nl}}M^{\alpha_{nm}}T^{\alpha_{nt}}Q^{\alpha_{nq}} \end{aligned}\right\} \tag{16}$$

in which the $X$'s are dimensionless quantities, the factors M, L, T, and Q are the fundamental physical units and the $\alpha$'s are the dimensions of the $x$'s in these units. If for example $x_4$ is an inductance of 0.03 henry it may be written as

$$x_4 = 0.03\ L^2MQ^{-2} \tag{16a}$$

In this case $X_4 = 0.03$, $\alpha_{4l} = 2$, $\alpha_{4m} = 1$, $\alpha_{4t} = 0$, and $\alpha_{4q} = -2$.

16. For all numbered references, see list at end of paper.

It is necessary that any fundamental physical quantity be represented to the same scale throughout any given formula,[6] hence the choice of unit or base quantities in an expression must not introduce inconsistent scales for length, mass, time, or electric charge. Thus

$$\left.\begin{aligned}
\frac{x_1}{B_1} &= X_1\left(\frac{\mathrm{L}}{\mathrm{L}_0}\right)^{\alpha_{1l}}\left(\frac{\mathrm{M}}{\mathrm{M}_0}\right)^{\alpha_{1m}}\left(\frac{\mathrm{T}}{\mathrm{I}_0}\right)^{\alpha_{1t}}\left(\frac{\mathrm{Q}}{\mathrm{Q}_0}\right)^{\alpha_{1q}}\\
\frac{x_2}{B_2} &= X_2\left(\frac{\mathrm{L}}{\mathrm{L}_0}\right)^{\alpha_{2l}}\left(\frac{\mathrm{M}}{\mathrm{M}_0}\right)^{\alpha_{2m}}\left(\frac{\mathrm{T}}{\mathrm{T}_0}\right)^{\alpha_{2t}}\left(\frac{\mathrm{Q}}{\mathrm{Q}_0}\right)^{\alpha_{2q}}\\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\\
\frac{x_n}{B_n} &= X_n\left(\frac{\mathrm{L}}{\mathrm{L}_0}\right)^{\alpha_{nl}}\left(\frac{\mathrm{M}}{\mathrm{M}_0}\right)^{\alpha_{nm}}\left(\frac{\mathrm{T}}{\mathrm{T}_0}\right)^{\alpha_{nt}}\left(\frac{\mathrm{Q}}{\mathrm{Q}_0}\right)^{\alpha_{nq}}
\end{aligned}\right\} \quad (17)$$

In equations 17 the quantities $\mathrm{L}_0$, $\mathrm{M}_0$, $\mathrm{T}_0$, and $\mathrm{Q}_0$ are the base or unit values of the fundamental physical units which are associated with the base or unit values $B_1$, $B_2$, etc., of the derived quantities. The equations 17 are dimensionless because $x_1$ and $B_1$ have the same dimensions, L and $\mathrm{L}_0$ have the same dimensions, etc. If the first of equations 16 be divided by the first of equations 17, the second by the second, etc., the following equations result:

$$\left.\begin{aligned}
B_1 &= \mathrm{L}_0^{\alpha_{1l}}\mathrm{M}_0^{\alpha_{1m}}\mathrm{T}_0^{\alpha_{1t}}\mathrm{Q}_0^{\alpha_{1q}}\\
B_2 &= \mathrm{L}_0^{\alpha_{2l}}\mathrm{M}_0^{\alpha_{2m}}\mathrm{T}_0^{\alpha_{2t}}\mathrm{Q}_0^{\alpha_{2q}}\\
&\cdots\cdots\cdots\cdots\cdots\cdots\\
B_n &= \mathrm{L}_0^{\alpha_{nl}}\mathrm{M}_0^{\alpha_{nm}}\mathrm{T}_0^{\alpha_{nt}}\mathrm{Q}_0^{\alpha_{nq}}
\end{aligned}\right\} \quad (18)$$

Clearly the values of $\mathrm{L}_0$, $\mathrm{M}_0$, $\mathrm{T}_0$, and $\mathrm{Q}_0$ may be assigned in any manner whatever, but the bases $B_1$, $B_2$, etc., may be assigned only such as to satisfy equations 18. These equations therefore represent a set of restrictions on the $B$'s; they may be used to determine how many of the $B$'s may be independently assigned and to determine the relations from which the remaining ones may be calculated. The nature of the restrictions which these equations impose upon the selection of the $B$'s is more clearly seen if logarithms are taken:

$$\left.\begin{aligned}
\alpha_{1l}\log \mathrm{L}_0 + \alpha_{1m}\log \mathrm{M}_0 + \alpha_{1t}\log \mathrm{T}_0 + \alpha_{1q}\log \mathrm{Q}_0 &= \log B_1\\
\alpha_{2l}\log \mathrm{L}_0 + \alpha_{2m}\log \mathrm{M}_0 + \alpha_{2t}\log \mathrm{T}_0 + \alpha_{2q}\log \mathrm{Q}_0 &= \log B_2\\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\\
\alpha_{nl}\log \mathrm{L}_0 + \alpha_{nm}\log \mathrm{M}_0 + \alpha_{nt}\log \mathrm{T}_0 + \alpha_{nq}\log \mathrm{Q}_0 &= \log B_n
\end{aligned}\right\} \quad (19)$$

These may be regarded as a set of $n$ algebraic equations in the 4 variables ($\log \mathrm{L}_0$), ($\log \mathrm{M}_0$), ($\log \mathrm{T}_0$), and ($\log \mathrm{Q}_0$). Since in general 4 such equations are all that are required for the determination of 4 variables, it follows that not more than 4 of the $B$'s can be assigned independently. The general rules for the assignment of the $B$'s, which follow from the theory of linear algebraic equations,[1] are:

1. It is never possible to assign more than 4 independent bases.

2. Any 4 bases may be assigned independently only if the determinant formed of the exponents in the 4 dimensional equations for these quantities is not zero.

3. Any 3 bases may be assigned independently only if there is at least one third-order determinant in the exponents, contained in the 3 dimensional equations for these quantities, which is not zero.

4. Any 2 bases may be assigned independently only if there is at least one second-order determinant in the exponents, contained in the 2 equations for these quantities, which is not zero.

The above 4 provisos are the conditions for *dimensional independence* of the arbitary base quantities for a per-unit system.

EXAMPLE

Referring again to example II, let us regard the assignment of base or unit values to $v$, $r$, $i$, $L$, and $t$ in the light of the foregoing. The equation relating these quantities, as pointed out in equation 14*a*, is of the form

$$f(v, r, i, L, t) = 0$$

hence we require values for the bases $V_0$, $R_0$, $I_0$, $L_0$, and $T_0$ in the equation

$$f\left(\frac{v}{V_0}, \frac{r}{R_0}, \frac{i}{I_0}, \frac{L}{L_0}, \frac{t}{T_0}\right) = 0 \quad (20)$$

Using the same numerical values as before the dimensional equations for the variables and parameters are:

$$\left.\begin{aligned}
v &= V\,\mathrm{L}^2\,\mathrm{MT}^{-2}\,\mathrm{Q}^{-1}\\
r &= 20\,\mathrm{L}^2\mathrm{MT}^{-1}\,\mathrm{Q}^{-2}\\
i &= (5\sqrt{2}\sin 377t)\,\mathrm{L}^0\mathrm{M}^0\mathrm{T}^{-1}\mathrm{Q}\\
L &= 0.03\,\mathrm{L}^2\mathrm{MT}^0\mathrm{Q}^{-2}\\
t &= T\,\mathrm{L}^0\,\mathrm{M}^0\,\mathrm{T}\,\mathrm{Q}^0
\end{aligned}\right\} \quad (21)$$

As developed in equations 16 to 19 the bases must satisfy the equations

$$\left.\begin{aligned}
2\log \mathrm{L}_0 + \log \mathrm{M}_0 - 2\log \mathrm{T}_0 - \log \mathrm{Q}_0 &= \log V_0\\
2\log \mathrm{L}_0 + \log \mathrm{M}_0 - \log \mathrm{T}_0 - 2\log \mathrm{Q}_0 &= \log R_0\\
- \log \mathrm{T}_0 + \log \mathrm{Q}_0 &= \log I_0\\
2\log \mathrm{L}_0 + \log \mathrm{M}_0 - 2\log \mathrm{Q}_0 &= \log L_0\\
\log \mathrm{T}_0 &= \log T_0
\end{aligned}\right\} \quad (22)$$

It is known at the outset that not more than 4 bases can be assigned independently. Let us attempt to assign 4 independent bases, for example, $V_0$, $R_0$, $L_0$, and $T_0$. The determinant of the dimensional exponents is

$$D = \begin{vmatrix} 2 & 1 & -2 & -1\\ 2 & 1 & -1 & -2\\ 2 & 1 & 0 & -2\\ 0 & 0 & 1 & 0 \end{vmatrix} \quad (23)$$

In this determinant, row 3 minus row 4 is equal to row 2; hence the determinant is zero. It will be found that all other fourth-order determinants contained in equations 22 are also zero, thus rule 2 above restricts the assignment to 3 independent base values. Even in the assignment of these there is a further restriction. For example, is it not possible to assign $V_0$, $R_0$, and $I_0$ independently. The dimensional exponents for $v$, $r$, and $i$ form the array

$$\begin{vmatrix} 2 & 1 & -2 & -1\\ 2 & 1 & -1 & -2\\ 0 & 0 & -1 & 1 \end{vmatrix}$$

Because the second row plus the third row of this array is equal to the first row, any third order determinant contained within it is zero. Selection of independent bases for these quantities would violate rule 3 above. A more detailed investigation reveals that it is permissible to assign 2 independent bases in one of the groups $V_0$, $R_0$, $I_0$ or $T_0$, $R_0$, $L_0$ and one independent base in the other group, but that it is not permissible to assign all 3 in one group. This

is in agreement with the previous observation that $V_0 = R_0 I_0$ and $L_0 = R_0 T_0$.

## Inductively Coupled Circuits

Consider a pure turn ratio having $N_1$ turns on the primary and $N_2$ turns on the secondary. Such a device has the property of stepping up the voltage in the ratio $N_2{:}N_1$ and stepping down the current in the ratio $N_1{:}N_2$, the kilovolt-amperes remaining unchanged. The device is assumed to have no other properties. Let the ratio $N_1{:}N_2 = a$. If 2 circuits are coupled by means of such a turn ratio it is evident that a current $\mathbf{I}_1$ in the primary circuit is equivalent to a current $a\mathbf{I}_1$ in the secondary circuit

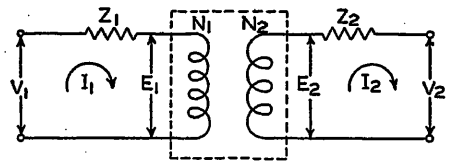

Figure 1

and that a voltage $\mathbf{V}_1$ in the primary circuit is equivalent to a voltage $\mathbf{V}_1/a$ in the secondary circuit. From this it follows that an impedance $\mathbf{Z}_1$ may be removed from the primary circuit providing an impedance $\mathbf{Z}_1/a^2$ is inserted in the secondary circuit. These principles are commonly used in referring transformer equivalent circuits to a given side of the transformer.

Suppose it be desired to express the quantities in 2 circuits coupled by a turn ratio in per unit. Referring to figure 1 the equations are

$$\left.\begin{aligned} \mathbf{V}_1 - \mathbf{Z}_1\mathbf{I}_1 &= \mathbf{E}_1 \\ \mathbf{E}_2 - \mathbf{Z}_2\mathbf{I}_2 &= \mathbf{V}_2 \\ a\mathbf{I}_1 &= \mathbf{I}_2 \\ \mathbf{E}_1 &= a\mathbf{E}_2 \end{aligned}\right\} \quad (24)$$

Combining equations 24 the following well-known single equation for the performance of the circuits is obtained:

$$\mathbf{V}_1 - (\mathbf{Z}_1 + a^2\mathbf{Z}_2)\,\mathbf{I}_1 = a\mathbf{V}_2 \quad (25)$$

Let us rewrite these equations in per unit. The quantities involved are voltages, currents, and impedances. As has been shown only 2 independent bases may be chosen. Suppose $\mathbf{V}_0$ and $\mathbf{I}_0$ be taken as the arbitrary bases, then $\mathbf{Z}_0 = \mathbf{V}_0/\mathbf{I}_0$. In per-unit terms we have

$$\mathbf{V}_{1pu} - (\mathbf{Z}_{1pu} + a^2\mathbf{Z}_{2pu})\,\mathbf{I}_{1pu} = a\mathbf{V}_{2pu} \quad (26)$$

which is identical in form with equation 25. Equation 26 is the result of setting up a consistent per-unit system in accordance with the methods outlined in the foregoing. Suppose however that instead of demanding a *consistent per-unit system* which yields per-unit quantities which satisfy the *same equations* as the ordinary quantities, we attempt to set up an *inconsistent per-unit system* which satisfies *simpler equations* than those satisfied by the ordinary quantities. Let the same base values as before be retained for quantities on the primary side (denote these by $\mathbf{V}_{10}$, $\mathbf{I}_{10}$, and $\mathbf{Z}_{10}$) and let new base values be used for the quantities on the secondary side in accordance with

$$\left.\begin{aligned} \mathbf{V}_{20} &= \frac{\mathbf{V}_{10}}{a} \\ \mathbf{I}_{20} &= a\mathbf{I}_{10} \\ \mathbf{Z}_{20} &= \frac{\mathbf{Z}_{10}}{a^2} \end{aligned}\right\} \quad (27)$$

Designating the new per-unit secondary quantities by primes we have

$$\left.\begin{aligned} \mathbf{V}_{1pu} - \mathbf{Z}_{1pu}\,\mathbf{I}_{1pu} &= \mathbf{E}_{1pu} \\ \mathbf{E}'_{2pu} - \mathbf{Z}'_{2pu}\,\mathbf{I}'_{2pu} &= \mathbf{V}'_{2pu} \\ \mathbf{I}_{1pu} &= \mathbf{I}'_{2pu} \\ \mathbf{E}_{1pu} &= \mathbf{E}'_{2pu} \end{aligned}\right\} \quad (28)$$

from which

$$\mathbf{V}_{1pu} - (\mathbf{Z}_{1pu} + \mathbf{Z}'_{2pu})\mathbf{I}_{1pu} = \mathbf{V}'_{2pu} \quad (29)$$

If the numerical values of the primary bases are taken as the rated values on the primary sides, then equations 27 give numerical values for the secondary bases which are also rated values. This selection of base quantities, although dimensionally inconsistent, effects a twofold simplification in the calculation of circuits involving turn ratios: the numerical values are held to convenient and readily interpretable sizes and the equations themselves become easier to write down. This principle can be used in a variety of practical problems in which turn ratios are involved: armature, field, and amortisseur relations in synchronous machines, transformers, etc.

## Calculation of Power Networks

One example of the above, commonly encountered in engineering practice, in which a considerable simplification is effected, is the calculation of the current and voltage relationships in power networks. Consider a simple

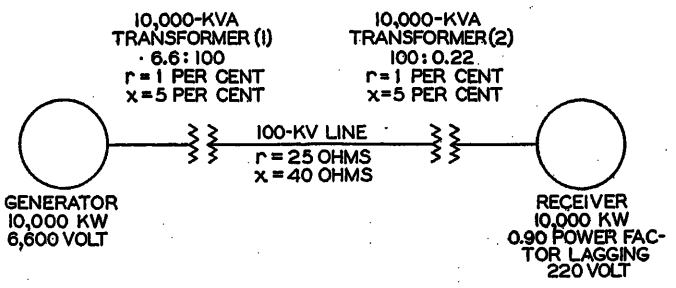

Figure 2

network in which a load or receiver is supplied from a distant generator by means of a transmission line having transformers at either end. Such a system is indicated in the single line diagram, figure 2.

Let it be required to calculate the generator terminal voltage necessary to maintain 220 volts at the receiver.

Divide the network into 3 parts separated by the turn ratios of the transformers. Choose a common kilovolt-ampere base $(\text{kva})_0 = 10{,}000$. Choose the rated voltage of each part as the voltage base of that part $V_{10} = 6{,}600$,

$V_{20} = 100{,}000$, $V_{30} = 220$. Then in per unit the data may be rewritten

Receiver: $Z_0 = 0.00484$, $R_{pu} = 0.90$, $X_{pu} = 0.435$

Transformer (2): $Z_0 = \begin{cases} 0.00484 \\ \text{or,} \quad R_{pu} = 0.01, X_{pu} = 0.05 \\ 1{,}000 \end{cases}$

Line: $Z_0 = 1{,}000$, $R_{pu} = 0.025$, $X_{pu} = 0.04$

Transformer (1): $Z_0 = \begin{cases} 1{,}000 \\ \text{or } 4.35\ R_{pu} = 0.01, X_{pu} = 0.05 \end{cases}$

Total per-unit impedance $= 0.945 + j0.575 = 1.11 \angle 33.5°$. Since the current is unity the voltage required is $1.11 \times 6{,}600 = 7{,}326$ volts.

## An Electromechanical Example

In synchronous-machine calculations it is customary to choose as base armature voltage the rated voltage of the machine and as base armature kilovolt-amperes the rated kilovolt-amperes of the machine. This results in a base armature current which is the rated current of the machine. Base time is usually taken as seconds per radian at normal frequency. In certain stability calculations it is necessary to write a differential equation for the acceleration of the rotor of a synchronous machine in terms of the difference between the electrical and mechanical torques and the moment of inertia of the armature. In mks units the equation is

$$J\frac{d^2\theta}{dt^2} = \Delta T \tag{30}$$

in which

$J$ = moment of inertia in kilogram square-meters, or in joule seconds-square per radian-square
= angular displacement from synchronism in mechanical radians
$t$ = time in seconds
$\Delta T$ = difference between electrical and mechanical torques in joules per radian

Since the associated electric circuit will in general be calculated in per unit, equation 30 should also be expressed in per unit.

Three independent bases [$(\text{kva})_0$, $V_0$, and $T_0$] have been specified; is it permissible to assign base values for moment of inertia or torque, or are these calculable from the 3 already assigned? In order to answer this question write down the determinant of the exponents taken from table I for kilovolt-amperes, electromotive force, time, and moment of inertia. The determinant is

$$D = \begin{vmatrix} 2 & 1 & -3 & 0 \\ 2 & 1 & -2 & -1 \\ 0 & 0 & 1 & 0 \\ 2 & 1 & 0 & 0 \end{vmatrix} \begin{matrix} \text{(kilovolt-amperes)} \\ \text{(electromotive force)} \\ \text{(time)} \\ \text{(moment of inertia)} \end{matrix} \tag{31}$$

If the third row be multiplied by 3 and added to the first row the fourth row is obtained; hence the determinant is zero. It is therefore not permissible to select a base moment of inertia $J_0$ independently. It must be calculated from the relation

$$J_0 = (\text{kva})_0 T_0^2 \tag{32}$$

In the case of torque we find that the dimensional exponents for torque may be obtained by adding the exponents for kilovolt-amperes and time, hence

$$T_0 = (\text{kva})_0 T_0 \tag{33}$$

In terms of these bases equation 30 becomes

$$J_{pu}\frac{d^2\theta}{dT_{pu}^2} = \Delta T_{pu} \tag{34}$$

in which $J_{pu} = J/J_0$, $T_{pu} = t/T_0$, $\Delta T_{pu} = \Delta T/\Delta T_0$, and $\theta =$ angular displacement in *electrical radians* (on account of the choice of seconds per electrical radian as base time).

Instead of using $J_{pu}$ in stability calculations it is customary to use a quantity $H$ defined as twice the kinetic energy in the rotor per rated kilovolt-ampere. Since kinetic energy has the dimensions watt seconds, the quantity $H$ has the dimensions of seconds. To make equation 34 true if $H$ is substituted for $J_{pu}$ we must multiply by $2\ T_0 = 2/2\pi f = 1/\pi f$. The usual form of the equation is

$$\frac{d^2\theta}{dT_{pu}^2} = \frac{\Delta T_{pu}}{\pi f H} \tag{35}$$

Although this is not a complete per-unit system it has the advantage that $H$ is a readily measurable quantity. It can be shown that $H$ is the time in seconds required to bring the machine to rest from normal speed when normal full load is continuously applied.

## Dimensional Homogeneity in Per-Unit Equations

It is commonly accepted that a physical equation must be dimensionally homogeneous.[6,14] Therefore an equation which, although true numerically, seems not to "check" dimensionally requires special consideration. An equation often encountered in the machinery literature is an excellent example:

$$E = T\,p\psi + I \tag{36}$$

in which

$E$ = per-unit electromotive force in the field
$T$ = per-unit time constant of the field circuit (armature open circuited)
$p$ = derivative with respect to per-unit time
$\psi$ = per-unit field flux linkages due to the armature current
$I$ = per-unit current in the field

This equation is derivable from the differential equation

$$e_f = r_f i_f + L_f\frac{di_f}{dt} + \frac{d}{dt}(Mi_a) \tag{37}$$

This may be rewritten as

$$\frac{e_f}{r_f} = i_f + \frac{L_f}{r_f}\frac{di_f}{dt} + \frac{L_f}{r_f}\frac{d}{dt}\left(\frac{M}{L_f}i_a\right) \tag{38}$$

The quantity $L_f/r_f$ is a time constant and may be written $T$, hence we may write

$$\frac{e_f}{r_f} = i_f + T\left[\frac{di_f}{dt} + \frac{d}{dt}\left(\frac{M}{L_f}i_a\right)\right] \tag{39}$$

Let base resistance be taken as the actual resistance of the field circuit.

$$R_0 = r_f \tag{40}$$

and let the bases $E_0$ and $T_0$ be selected in any convenient manner. In per unit equation 39 is

$$\frac{E_{pu}}{R_{pu}} = I_{pu} + T_{pu}\frac{dI_{pu}}{dT_{pu}} \tag{41}$$

in which $I_{pu}$ is the total equivalent field current. From equation 40 $R_{pu}$ is unity, hence *numerically*

$$E_{pu} = I_{pu} + T_{pu}\frac{dI_{pu}}{dT_{pu}} \tag{42}$$

Note also that per-unit flux linkages are given by

$$\psi_{pu} = \frac{N^2Pi}{N^2PI_0} = I_{pu} \tag{43}$$

in which $P$ is the permeance in rationalized mks units.

Thus we have the numerical equation

$$E_{pu} = T_{pu}\,p\psi_{pu} + I_{pu} \tag{44}$$

which is the same as equation 36.

Although simplification of calculation may be effected by use of equation 44, this advantage is sometimes more than offset by the increased difficulty in interpretation. It is true that equations expressed in per unit are dimensionless; however, it is of great importance to preserve a notation which indicates the dimensional origin of the various terms of the equations.

# 1937 Index—Electrical Engineering and Transactions

This multientry annual reference index covers comprehensively the entire text content of the 12 issues of ELECTRICAL ENGINEERING published during 1937 and the identical content of the 1937 AIEE TRANSACTIONS, volume 56; the index covers also a supplement of 28 pages published in the TRANSACTIONS, which contains the following two papers not published in ELECTRICAL ENGINEERING:

1. FUNDAMENTAL CONCEPTS OF SYNCHRONOUS MACHINE REACTANCES, by B. R. Prentice (pages 1–21 of supplement).

2. PER-UNIT QUANTITIES, by Irven Travis (pages 22–8 of supplement).

A special effort has been made to provide effective correlation between references to technical papers and all published discussions of those papers. Discussions of many technical papers published during the latter part of 1936 were published in the early part of 1937, and hence appear in this current index. Likewise, many discussions of the later 1937 papers will be published early in 1938, and consequently will not be found among the references contained in this current index.

For convenience in use, this index is subdivided into the following general sections:

1. Technical subjects.
2. Authors, including the writers of discussions.
3. News items pertaining to Institute activities.
4. News items of a general nature.
5. Biographical (personal and obituary) items.

## Division I—Technical Subject Index

Abrasion—A Factor in Electrical Brush Wear. Hessler.....8–12 and 16
Disc. and closure..... 601
Accidents, Electrical. Kouwenhoven.1077–79
Activity, Branch. MacCutcheon.... 777
Administration of Federal Power in the Pacific Northwest, Proposals for. Carpenter..... 964–7
After Graduation—What Then? Hammond..... 418–19
AIEE 1937–38 Budget, The. Harrison..... 1433
Air-Gap Reactances, Characteristic Constants of Single-Phase Induction Motors. Part I. Morrill.. 333–8
Disc. and closure..... 1312
Air, Workers in New Chicago Building to Breathe Electrically Cleaned. (Filler)..... 1378
Aircraft, Present-Day and Probable Future Electrical Applications in. Boughton..... 959–63
A-C Characteristics of Dielectrics—II. Banos. (Dec. 1936, p. 1329–37)
Disc. and closure..... 477
A-C Machines, Operational Solution of. Miller. (Nov. 1936, p. 1191–1200)
Disc..... 1028
A-C Motor Protection. Kuhn..... 589–93
Disc. and closure..... 1306
Algebra Applied to 3-Phase Circuits, Dyadic. Sah. (Aug. 1936, p. 876–82)
Disc. and closure.....610, 1030
Algebra in Transformer Circuits, Tensor. Bewley. (Nov. 1936, p. 1214–19)
Disc..... 614
Alternator, Double-Line-to-Neutral Short Circuit of an. Smith, Weygandt.....1149–55
Alternator Short-Circuit Currents Under Unsymmetrical Terminal Conditions. Miller, Weil.....1268–76
Alternator-Voltage Regulator Utilizing a Nonlinear Circuit, An. Mayne. .....462–4 and 476
American Engineering Council, The. Potter.....1082–1084
Amplification Loci of Resistance-Capacitance Coupled Amplifiers. Seletzky. (Dec. 1936, p. 1364–71)
Disc. and closure..... 877
Analysis of Copper-Oxide Rectifier Circuits, An. Huss.....354–60 and 366–7
Analysis of Series Capacitor Application Problems. Butler, Concordia 975–88
Analysis of the Shaded Pole Motor, An. Trickey. (Sept. 1936, p. 1007–14)
Disc. and closure..... 612
Analyzer Solution of Multiple Unbalances, Network. Kimbark.....1476–82
Apparatus Noise Measurement, A Proposed Test Code for. Committee Report.....1079–82
Application of Arresters and the Selection of Insulation Levels. Foote, North..... 677–82
Disc. and closure.....1293, 1407
Application of Spill Gaps and Selection of Insulation Levels. Melvin, Pierce..... 689–94
Disc. and closure.....1290, 1408
Application Problems, Analysis of Series Capacitor. Butler, Concordia..... 975–88
Applications in Aircraft, Present-Day and Probable Future Electrical. Boughton..... 959–63
Applications in Bethlehem's 72-Inch Strip Mill, Electrical. Egan..1105–1114
Approximating Potier Reactance. Beckwith..... 813–18
Disc. and closure..... 1318
Arc Characteristics Applying to Flashing on Commutators. Hellmund. 107–13
Disc. and closure..... 603
Arrester, Characteristics of the New Station-Type Autovalve Lightning. Roman..... 819–22
Arresters and the Selection of Insulation Levels, Application of. Foote, North..... 677–82
Disc. and closure.....1293, 1407
(ASA) Revision of Standards for Railway Motors. Storer..... 312–13
Atoms and Spinning Electrons, Spinning. Darrow.....1228–35
(Auditory Perspective) Sound Reinforcing System for Hollywood Bowl..... 412–13
Automatic Boosters on Distribution Circuits. Olmsted. (Oct. 1936, p. 1083–96)
Disc. and closure..... 893
(Automatic Stations) An Alternator-Voltage Regulator Utilizing a Nonlinear Circuit. Mayne..... .....462–4 and 476
(Automatic Stations) Electrical Water-Level Control and Recording Equipment for Model of Cape Cod Canal. Hazen..... 237–44
Autovalve Lightning Arrester, Characteristics of the New Station-Type. Roman..... 819–22
(Aviation) Electricity Aloft. Johnston..... 406–10
